THE PSYCHOLOGY OF LANGUAGE

The psychologist tends to look at language in the first instance as he would look at any other problem area. Unique or special problems are confronted as they arise, but there is no unequivocal case for or against a special psychology—one created for language alone. The best, or, perhaps, the only way to discuss the psychology of language at this time is to describe how psychologists have been looking at it. Much of what can be said receives consideration in other articles in these volumes. The present one can serve as an introduction to the other articles, and it will be concerned, in part at least, with an attempt to set the framework which marks psychological studies of language. Certain more specific problems will also be treated—problems which represent some of the writer's special interests and which are unlikely to receive extended discussion elsewhere.

Early interests of psychologists in language

Studies of language—or, as psychologists prefer to call it, verbal behavior, which applies to both spoken and written forms—began very early in the postphilosophical period in psychology. Several themes may be identified (see Carroll 1953).

The "word-association experiment." First, Wilhelm Wundt, often called the first experimental psychologist, was interested in language—but more

from a naturalistic than from an experimental point of view. However, workers in his laboratory early took an interest in the "word-association experiment," the origin of which is usually attributed to Sir Francis Galton. Galton's pioneering work was carried out with himself as subject: he wrote down stimuli on slips of paper and later looked at each slip (on more than one occasion) and recorded the thoughts that were thereby elicited. He also timed these reactions and noted the tendencies for the same or different thoughts to occur on the several occasions on which he looked at each slip (Warren 1921).

The "word-association experiment," despite its early entrance into the psychological laboratory (some of the results obtained are still cited today; see e.g. Woodworth [1938] 1960), soon figured more prominently in clinical diagnostic work than in the experimental laboratory. While the associations made by pathological subjects and by normal subjects were often found to differ, on the average, the association method never reached a dominant position in the armamentarium of clinical techniques, in the detection of "complexes," or, except in classroom demonstrations, in the detection of "guilty knowledge," although it was applied to all of these problems. It is safe to say that until about 1950 it had fallen into relative neglect. In the years since 1950, however, interest in association methods has reached a very high level because of the demonstrated value of measured associations in predicting other verbal behavior [see Marshall & Cofer 1963; Noble 1963; see also *ANALYTICAL PSYCHOLOGY and the biography of JUNG*].

Verbal learning. The study of verbal learning was begun in the laboratory almost as early as the

word association method. Hermann Ebbinghaus reported the first experiments in a classic monograph in 1885. Ebbinghaus, however, was not really concerned with general questions of language or verbal behavior; he was interested instead in the formation of associations, and he attempted to prevent such factors as meaning, meaningfulness, and connectedness from influencing his results by inventing and using the nonsense syllable. A vast outpouring of work on verbal learning followed Ebbinghaus' pioneer efforts (see e.g. McGeoch [1942] 1952; Conference . . . 1961; Conference . . . 1963), but current opinion is that verbal learning cannot be divorced from features of the subject's usual language. [See LEARNING, *article on* VERBAL LEARNING; and the biography of EBBINGHAUS.]

Mediational processes. A third concern in psychology's study of verbal behavior is the role verbal processes may have in *mediating* between stimuli and responses. Quite early (in the 1890s) there was an interest in "mediate association," the notion that while two terms may not be related directly to one another they may be linked by a third term. Thus, justice and war may not be directly associated, but they may be related if, when one thinks justice, he also thinks peace. The latter may lead to the word "war," thus serving to mediate between justice and war.

Mediational processes, especially verbal ones, have provided a mechanism whereby objective and behavioristic psychologists can account for forms of thought, stimulus and response equivalence, and other phenomena which are otherwise refractory to a simple analysis in terms of stimulus and response (Goss 1961a). Much of the impetus to this way of thinking came from studies of semantic conditioning, both in Russia and in the United States (Osgood 1953; Jenkins 1963), in which verbal behavior is given an important role in the control of other behavior (Lurii 1961; Dollard & Miller 1950). There has also been great interest in the possibilities for altering verbal behavior itself (and thus perhaps its control over other behaviors) by means of reinforcement and nonreinforcement (Krasner 1958) or by other means (Cofer 1957; 1960).

Psycholinguistics. The fourth, and final, major trend appeared in the early 1950s and was a convergence of psychology (especially learning theory), descriptive linguistics, and information theory. This convergence was facilitated by the Social Science Research Council and the Carnegie Corporation (Carroll 1953). Essentially, it amounted to the bringing together of linguists and psychologists

(see Osgood 1963; Osgood & Sebeok 1954) so that each group could become familiarized with the techniques and concepts of the other. As a result, an interdisciplinary "field"—psycholinguistics—has sometimes been identified, although its methods and concepts perhaps tend to be more aggregations than mergers of the concepts and methods of the disciplines. "Psycholinguisticians" tend to retain their primary identifications as linguists or as psychologists. The development of the notion of a "generative grammar" (Chomsky 1957) in linguistics may well alter the character of psycholinguistics. [See LINGUISTICS.]

It must be pointed out that what has been said implies very little concerning language as a process of interindividual communication. It is obvious that communication is a major function of language, but from the present vantage point it seems that matters other than communication per se have engaged the interests of the major psychological students of language or verbal behavior, although studies of communication processes do go on. Also neglected in the foregoing account is speech perception and speech pathology, the study of which can yield important and useful information on a variety of problems. [See LANGUAGE, *article on* SPEECH PATHOLOGY; PERCEPTION, *article on* SPEECH PERCEPTION.]

Viewpoints concerning mediational events

A major theoretical concern among psychologists interested in verbal behavior has been the implicit events which may accompany overt speech production or writing. Cofer and Foley (1942) suggested that a mediating response underlies cases of stimulus equivalence (or transfer or generalization) among stimuli which are physically dissimilar. Thus, if a response is learned to a word like "fashion" and it transfers, without further training, to the word "style" or "mode," the transfer cannot be explained on the basis of the visual appearance or the sound of the words. The argument advanced, in essence, was that each of these words elicits, as a result of prior experience, a common reaction. If this reaction occurs when fashion is presented, it will be associated with the new response being learned to fashion. Since style and mode also elicit the common reaction, its occurrence when they are presented would also result in the appearance of the response newly learned to fashion. The common reaction mediates the transfer. Cofer and Foley stressed the relation of synonymy among words as an indication of the existence of common mediating reactions among them, but they also

spoke of interword associations in such a way as to suggest that associations, also, might serve as mediators.

Osgood's views—representational mediation. Osgood (1953; 1961) has made the mediating reaction the basis of a theory of meaning. Two words mean the same thing to the extent that they share the capacity to arouse the same *representational mediator*. The conception is that, with respect to an object, there is behavior, R_i (for total behavior). A sign, e.g., a word, may be acquired in relation to the object; but to have meaning with reference to the object the sign must arouse some representative part of the R_i made to the object. The representational part would ordinarily be those features of R_i which can readily be detached from the total and occur implicitly without interfering with other behavior.

This formulation led Osgood to make certain distinctions among word relations with respect to meaning. Thus, contrasting or opposite words (antonyms) cannot share common mediators and hence cannot have common meanings. This is because R_i with respect to objects or events must be very different in the case of antonyms. The representational mediators, in turn, would then be very different for antonyms. Thus, Osgood is forced to explain the fact that antonyms are often highly associated in word association tests (e.g., black-white, up-down) on the basis of a rote verbal habit rather than on the basis of common representational mediators. Similarly, he took the position that the existence of interword associations does not demonstrate, generally, the presence of common meanings. He also seemed to hold that transfer and generalization should ordinarily be predicated on common representational mediators rather than on common associations.

The semantic differential. As an index of a representational mediator, Osgood (see Osgood et al. 1957) emphasized the *semantic differential*. This is a technique by which a given word or concept (e.g., baby) is rated by a subject on each of a number of seven-point rating scales, the extremes of which are defined by polar adjectives. Thus, scales appear whose extreme points are designated by such adjective pairs as hot-cold, bad-good, active-passive, tense-relaxed. Factor analysis of the intercorrelations among such scales has usually yielded three more basic dimensions—evaluative (e.g., bad-good), activity (e.g., active-passive), potency (e.g., strong-weak). It is possible to describe a given word in terms of where its ratings fall in a semantic space defined by these three (and

perhaps other) dimensions. As these dimensions are believed to characterize the representational mediator, they are an index of its meaning. Osgood has referred to this as connotative (or emotional) meaning in contrast to denotative meaning.

Among psychological investigators of verbal behavior, Osgood has perhaps been the leader in emphasizing that meaning is a critical factor in verbal behavior and that a satisfactory account of language must deal with it. Others have not been convinced. Skinner (1957) has written a psychology of language in which the concept of meaning does not enter and which treats verbal behavior as a case of the operant. Skinner is concerned with the analysis of this operant (and the classes into which it may be divided) in terms of the variables (reinforcement, stimulus control, deprivation, aversive conditions) which control its strength. This is essentially a descriptive or positivistic procedure, representing an extrapolation of notions developed in the animal laboratory.

Association in mediation. More closely associated with the mainstream of the psychological study of verbal behavior, however, have been the investigators who have emphasized interword associations as the important problem. They have insisted that the test of what is important is not whether a conception explains meaning. Rather, they have argued that the extent to which predictions can be made of the behavior of words in a variety of situations is critical. In other words, they have held forth not the criterion that a conception of verbal behavior explains (or ignores) meaning but the criterion that a theory of verbal behavior must accept measures and procedures which correlate well with other phenomena in the verbal realm.

To give this approach (it can hardly be called a theory) some concreteness, we may describe an experiment made a number of years ago at the University of Minnesota (see Jenkins 1963 for references and discussion). This experiment (and many others as well) was designed, in part, to determine whether meaning (in Osgood's sense) or association is a more effective variable in predicting transfer in certain situations. Before discussing the experiment, we may turn first to a discussion of contemporary procedures of association tests.

Association tests. The word association test, as it has been typically used, consists of a list of words to which a subject reacts, one at a time, by saying or writing down the first other single word that comes to mind when he sees or hears a list (stimulus) word. This process is called free association

since no restriction is imposed on what response the subject can give, save that his response must be a single word and that repetitions of the stimulus word are prohibited. Despite its name, the procedure is not to be confused with the free association procedure as used in psychoanalysis: the two techniques differ widely.

The word association test is usually given to a number of subjects (from fifty to one hundred are considered a minimum for the establishment of norms), and their responses are tabulated for each stimulus. When such tabulations are made (and the stimuli used are relatively common words) the typical result is this: one word is given by a substantial number of subjects, another by somewhat fewer subjects, a third by still fewer subjects, and so on until words are found that are given by only one subject. An illustration will clarify this situation. Suppose the stimulus word is "length," and we obtain responses from 56 subjects. In such a sample the most frequent, or primary, response is width, occurring 18 times (32 per cent), the next is long, occurring 5 times (9 per cent), the next are height and measure, tied at 4 occurrences each, and there are 6 responses, each occurring twice—short, depth, foot, line, measurement, distance. In addition, there are 13 responses each occurring but a single time.

This set of associations, and others like it, is often termed an association hierarchy, because the responses differ and may be ordered in accordance with their frequencies of occurrence to the stimulus word. Such hierarchies may differ in a number of properties. Thus, the primary frequency may vary considerably (e.g., table elicits chair as a primary from about 75 per cent of a group of U.S. college students, in contrast to the 32 per cent indicated above), and the difference between the primary and other responses themselves may vary. Likewise, the number of different words given to a stimulus varies; usually the higher the primary frequency the fewer other words there are, a fact dictated by arithmetic if we are dealing with a constant sample size.

These differences in associative frequency have been taken as a measure of association or habit strength, not only for the group, but, by inference, for the individual. Though it is by no means a certain inference, there is evidence which justifies it (cf. Russell 1961). At any rate, a number of experiments have been predicated on this inference.

The dominant association to length, as we have seen, is width. The dictionary records a number of meanings for the word "length," but width is not among them; measure, measurement, and distance

are, however, approximations to the dictionary statement of some of the meanings of length. We may say that width is a prominent *associative* meaning of length, if we wish to, but it certainly does not qualify in a dictionary or denotative sense as a meaning of length. This, of course, illustrates Osgood's argument that associations are not the same as meaning.

Predictive value of associations. The question, however, may still be raised whether the associations are effective in mediating transfer (and other phenomena) and, if they are, how they compare with synonyms in doing so. To answer this question, the following experiment was performed.

Two lists were constructed, each consisting of a series of word pairs. The subject was required to learn the two lists in succession, and the interest lay in the transfer effects of learning the first list upon learning the second list. Response members of the pairs in the two lists were related in two ways. Some responses were antonyms, but highly associated; since meaning has been ruled out by Osgood as a factor in the interrelation of antonyms, these pairs test the role of association. Other response members of the pairs were synonyms which, according to the word association test, were not associated. These test the capacity of meaning to mediate transfer without association. There were also control pairs, in which the response members of the two lists were neither synonyms nor associates. Table 1 shows the general experimental plan. When compared to control pairs in List 2, the pairs having associative and synonym relations with pairs in List 1 showed the effects of positive transfer in List 2. The associated pairs tended to be learned in a somewhat superior fashion than the synonymous pairs. In this experiment, then, both the postulated factors were effective. One can say that common meaning may effect transfer but that transfer can occur without it if suitable associations are present.

Table 1 — Experimental plan

CONDITION	LIST 1	LIST 2
Associated	eagle-sickness	eagle-health
Synonyms	mutton-long	mutton-tail
Controls	needle-king	needle-close

Many other experiments have been carried out which have explored and demonstrated the role of associations in a variety of situations. Among the situations studied have been free recall, list learning and recall, semantic generalization, recognition of words (in the context of other words) after very brief or inadequate presentations, verbal discrim-

ination, transfer, and concept formation (for references see Deese 1961; Jenkins 1963; Cofer 1957; 1960; and Marshall & Cofer 1963). The role of meaning has also been studied in some of these situations, and some conflict has arisen over whether meaning or association is the better concept or whether one can be reduced to the other (see Bousfield 1961; Osgood 1961). Since the role of mediation is critical to this work, whether interpreted in terms of meaning or association, a good deal of effort has been devoted to basic mediational processes and mechanisms (Jenkins 1963).

Associations in other tasks. Two further areas of inquiry may be discussed to demonstrate the interest of psychologists in the role of associations in such tasks as concept identification and problem solving.

Underwood and Richardson (see Marshall & Cofer 1963) selected a large number of words, to each of which they obtained "sensory" associations from a large group of college subjects. The subjects were carefully instructed as to the kind of association they were to give; thus it was pointed out that to such a stimulus word as "apple" responses like red, sour, or round would be appropriate; responses like tree, fruit, or seed would not meet the criteria for a sensory association. To each stimulus, sensory associations were arranged in a hierarchy according to frequencies, called "dominance levels" by the investigators.

It is possible then to present several words to a new group of subjects, each word having a sensory associate in common with the other words of the set. The subject is asked what these words have in common. For example, one might present the words "chalk," "milk," "paste," and "shirt" and ask what they have in common or in what way they are similar. The instructions here would not mention or suggest sensory attributes. An answer for the set just mentioned might be that they are or can all be white. The subjects are more successful in finding the expected solution for sets with high dominance levels than for sets with low dominance levels.

This finding suggests that in tasks of this kind solution will be more likely if the instances suggest the answer than if they do not. More generally, it is consistent with the idea that problem solution often derives from responses to the materials available. If the materials suggest available and appropriate responses, solution will be quick; if they do not, or if they suggest inappropriate or incorrect responses, solution may be delayed, impeded, or prevented altogether.

A somewhat similar analysis may be made of an experiment by Judson and Cofer (see Cofer 1957).

These investigators developed a number of four-word items; in each item, the subject was to exclude the word that did not go with or belong with the others. The critical items had two possible solutions. Thus, the item

skyscraper temple cathedral prayer

can be solved by excluding prayer, as it is not a building, or by excluding skyscraper, as it has nothing to do with religion. In the investigation carried out, an important factor found to determine solution was the word order of the item. As the item is shown above, prayer is excluded more often than skyscraper. If, however, the positions of prayer and skyscraper are interchanged in the item as presented, then skyscraper is excluded more often than prayer. Evidently, associations are initiated by the first word of the item and reinforced by the next two words (which are ambiguous in that they refer both to buildings and to religion) so that the last item is typically seen as not belonging. With highly religious persons, however (as measured by church attendance), the nonreligion item tends to be excluded no matter what its position is. Thus, while word order itself is important to the dominance of the concept to be identified (and thus to the word to be excluded), dominance can also arise from other, perhaps more personal, sources.

Associations should influence behavior over a period of time if their importance is great. A demonstration that is relevant was made by Judson and Cofer (see Cofer 1957). The procedure was divided into two parts, separated by a six-week interval. In part 1, each subject was asked to give ten free associations to each of ten stimulus words. Only one of these sets of associations was used later, however. Suppose one stimulus word was music and the first four associates given by one subject were tune, song, instrument, and melody. In part 2, for this subject, tune was presented on a card along with three other words (each on a card) that were new to the experiment. The subject was told to pick one of the four words. If he was "correct" (i.e., he chose tune) he was told that he was right. If he was "wrong" (i.e., he picked one of the other words), he continued to pick until he chose tune. After performing satisfactorily on this set of cards, he was then shown four more cards containing song and three new words. This time, he simply made a choice, with no information being given as to its correctness. Then he was shown four more cards, containing instrument and three new words and made a choice (without information); then melody with new words and so on until his sequence of ten associates was used up. The question

was, would the subject choose more often the words that he had associated with music after the first response (tune in the example) was said to be correct than he would choose the new words which were not part of the associative chain? As compared to the control group, the subjects answered this question affirmatively, indicating that the chain established in part 1 was still intact and that subsequent choices were influenced by the designation of the first word of the chain as correct.

Another way of investigating the role of associations in problem-solving behavior was used by Cofer, Judson and Gelfand (see Cofer 1957). In this experiment, the subjects were asked to solve certain problems. Prior to attempting the problems, the subject was taught several short lists of words. One of the lists contained a sequence of words, which, if active in the subject's mind at the time of problem solving, could influence the kind of solutions used in solving the problems. The results were suggestive, if not definitive. That is, for male subjects at any rate, the frequency with which one particular solution appeared for each task was augmented (as compared to controls), and this solution was the one to which the word list was related.

These experiments on concept formation and problem solving do not cover the entire range of these phenomena but, so far as they go, they do suggest that verbal associative processes can have an important effect in these tasks. And experiments such as these illustrate very pointedly what is meant by the role of verbal responses in mediating and controlling other behaviors. [See CONCEPT FORMATION and PROBLEM SOLVING.]

Work of the kind we have just described illustrates the influence of association tests, learning theory, and the interest in mediation processes in the control of behavior. Our description should be clear on one point: much of what we have said has been concerned essentially with single words and their relations to one another. Language involves more complex arrangements of words than this, and in psychology some attention has been paid to these complexities. Both linguistics and information theory contribute knowledge and techniques to considerations of this problem of complexity.

Contributions of information theory

Information or communication theory has contributed, in addition to a model of the communication process and a means of measuring the amount of information transmitted, the important concept of redundancy. In successive segments of a se-

quence of words taken from normal English, there are or may be dependency on what has gone before. In such cases, the listener (or reader) can often predict accurately what is to come, and when it comes its occurrence does not contribute any information (i.e., resolve any uncertainty) over and above what the listener or reader already has. [See INFORMATION THEORY.] Some of this redundancy arises from structural features of the language; other aspects of it may arise from semantic (associative?) features. In the sentence "Tom went to the ____" there are many items (such as movie, play, concert, game, exhibit) which can be inserted in the blank with equal appropriateness. However, all of them are nouns; we cannot insert pronouns, adverbs, adjectives, verbs, conjunctions, and prepositions if only one word is to be placed in the blank and the sentence is to end with that word. This is an example of structural redundancy: our choice is limited to nouns in filling the blank. We cannot use just any word in the language to do so. As the noun class contains a very large number of items, we still have many choices but we are, nonetheless, restricted by the grammatical situation (here a prepositional phrase which contains an article before the blank) to selection among those words which have the privilege of occurrence in the situation.

In many situations, it is easier to fill in blanks when they stand for items that have chiefly structural rather than semantic significance. Thus, it is more likely that the blank in the following "Tom ____ going to the play" will be replaced with the word "is" or "was" than it is that the blank in the first version would be replaced by any of the noun alternatives listed. There is, we may say, more redundancy in the case of *is* or *was* than there is in the blank in the noun phrase, although there is redundancy there also. With content words (nouns, adjectives, verbs, or adverbs), the semantic or associative context often severely limits the possible choices. Thus, in the sentence "Tom went to read the part in the ____" few choices (play, drama, for example) remain to the reader or hearer; redundancy here is high.

One of the advantages for learning that connected discourse has over unconnected words is conferred by its redundancy, both structural and semantic (Deese 1961). The influence of structural redundancy is perhaps confined to strings of words in which some features, at least, of the language are preserved. Strings of unrelated words, however, may be associatively or semantically related; thus there may be some redundancy in such terms.

It is clear that redundancy is an important feature of language; it is probably essential to accurate communication (especially in noisy channels), and, for memory, it is very helpful that large amounts of material can be coded (thus reducing the load on memory) in terms of redundant features (Miller 1956). That language is often used to code or categorize (Brown 1958) the environment is perhaps a feature of the greatest importance to intellectual functioning and to the role of language in the control of behavior.

Contributions of linguistics

It is probably fair to say that linguistics has had its greatest impact on psychology because of its knowledge of the structure of language and the rules that govern the structure. Phonemic and morphemic analysis has been instructive, but morphology and syntax are perhaps more provocative.

There are at least two fundamental issues that morphology and syntax raise for a psychology of language. First, it is clear that no theory of verbal behavior which confines itself to semantic and associative relations among words alone is complete. Mechanisms must be developed to cope with semantic and associative changes that undoubtedly occur in the context of other words, and syntactic restraints must be an important aspect of this context. Furthermore, no psychological theory of morphology or syntax has been presented as yet. Analysis so far has largely been confined to specific cues in speech or writing which might elicit word inflections or specific syntactic forms (Goss 1961*b*).

The second issue arises from the fact that at a descriptive level it is clear that speech regularities appear very early in the development of the child (Brown & Fraser 1963). Furthermore, many rule-abiding features of speech are known to occur widely, even though the speakers are unaware of the rules or of the fact that they are following rules. Young children display the operation of a general rule when they pluralize goose incorrectly as geoses or form the past tense of the verb "take" as "taked." Perhaps more subtle examples are found in the speech of adults. We all recognize that there is something wrong with the expression "the sheer two silk stockings" and would prefer to say "the two sheer silk stockings." We would have difficulty in formulating the rule that makes one expression acceptable, the other not. Despite its semantic nonsense, we can recognize the grammatical correctness of Chomsky's (1957) famous sentence, "colorless green ideas sleep furiously," or make the appropriate substitutions of nouns, verbs, and mod-

ifiers in such strings as "the glibs duxed the neglan gojeys." Semantic factors are not essential to the identification of grammaticality or to the identification of parts of speech.

The facts are, then, that morphological and syntactical principles govern much speech and writing behavior and that many of them cannot be verbalized by a large number of adults and appear in the speech behavior of young children without explicit instruction. These features suggest that a psychological theory or account of morphology and syntax may have to include concepts of a higher order than those of stimulus and response and that explicit coding responses cannot be invoked to mediate these phenomena of grammar.

Structural linguistics has provided descriptions of these phenomena and has described the regularities that prevail in language. However, it has not presented a theory of the behavior involved. Recently, Chomsky (1957) and Miller (1962) have argued for a new conception.

This conception holds that, in addition to a phrase-structure grammar, there is also a set of transformational rules which, when used, modifies a statement from one type to another including the necessary morphophonemic changes. Thus, a sentence model exists which appears to be the basic form (the kernel) of adult utterances, but it is transformed systematically, as needed, by the use of transformational rules like the interrogative, the passive, the negative, and so on. More than one rule may be applied, as when a simple declarative sentence becomes a passive interrogative negative. For example, "Tom hits the girl" would become "Is not the girl being hit by Tom?" by the application of the appropriate transformations.

Chomsky, a linguist, has been explicit in asserting that a simple stimulus-response formation and habit utilization theory cannot, in his opinion, cope with this conception of grammar. Miller, a psychologist, seems to agree, and while he thinks work on association is important, he believes that the mechanisms underlying the transformational grammar can hardly be of the associational kind. A psychological theory of the development and use of transformational grammar has not been formulated, but if these authors are correct it would presumably involve high-order processes not readily reducible to association or meaning.

We have surveyed some of the major interests and problems characterizing psychologists' work on language. Beginning with the historical trends in the psychological study of language, we have con-

centrated on mediational processes, conceived from both a meaning and a word-association point of view. While some progress on problems related to mediational processes has been made, many questions and further problems remain. Psychological understanding of language in the sense of connected words has not progressed very far, although concepts and methods of information theory and linguistics have been found useful. Whether the rule using that is evident in the verbal behavior of both children and adults, conceived either in terms of conventional morphology and syntax or in terms of transformational grammar, can be reduced to the concepts of contemporary learning theory is a question to be decided in the near future.

II

LANGUAGE DEVELOPMENT

Language development refers to the child's acquisition of his first language, usually under informal natural conditions. By the end of the first four years of life, children have mastered the essentials of this most distinctively human attribute. Given normal hearing and a normal brain, variations in rates of mastery are small. Indeed, so gifted in language learning are they that many children become skilled in more than one language in their early years. The evolution of a child's knowledge of his language is basic to his intellectual and social development, yet explanations of this process make demands on theories of human learning which have not yet been met.

Historical aspects. Studies of child language development in modern times fall into three phases. The first studies in the nineteenth century consisted primarily of parental diaries. Authors trained in linguistics (Gvozdev 1961; Leopold 1939-1949) have continued to use case studies. More than any other form of behavior, language reveals obvious internal patterning, and linguists have been loath to lose sight of these patterns by pooling quantitative measures of output. In the second phase of research, carried out by psychologists, standardized measuring methods of large samples were emphasized (McCarthy 1954). For the most part these studies have been atheoretical and have been concerned with variations in performance with age, sex, race, social class, and so on.

A landmark in modern research was Velten's (1943) application of Jakobson's (1941) theory of phonemic development. This theory proposed that changes in each child's linguistic system followed an orderly sequence of increasing differentiation of significant features; thus it related language development to perceptual development and provided a theoretical framework which made comparison of

children in different linguistic environments possible.

Subsequent research, particularly on phonology and grammar, is a product of the mating of psychology and linguistics. The differences from the preceding phase lie in the later work's sensitivity to linguistic theories, respect for the systematic nature of the child's linguistic knowledge, and emphasis on inferences about the structures or rules which underlie the observed situational changes in verbal behavior.

Prelinguistic phase of infancy. By the end of the first year of life, the average child understands some adult speech and can execute some directions. At first, he merely responds to adult sounds by attention and then by making sounds himself. Later he comes to recognize gross differences between voices and may distinguish intonational contrasts. His gradual discrimination of the critical features in the speech of adults is probably the most important aspect of language learning, yet almost nothing is known about the growth of comprehension.

The infant at first makes sounds which are closely tied to feeding and breathing. His vocalizations become increasingly triggered by vocal stimulation from others. In the first three months cooing comes to be highly associated with vocal stimulation and can also be increased in frequency if followed by other forms of adult responsiveness. On the other hand, the actual sounds uttered seem to be autogenous, since the sounds of deaf children and of children who hear are indistinguishable before six months.

Cooing gradually gives way to the consonant-vowel sequences and repetitive patterns which sound to adults like the syllables of their own language. During the babbling period, there is a rich variety of vocal play by the normal child. Sometimes he persists in making sounds which are idiosyncratic and not present in the speech around him. Further, he readily produces sounds and sequences in the adult repertoire which he will be unable to produce again for years after he begins to use language.

The role of babbling in language development is controversial. A child who lives in a linguistically stimulating environment may babble a great deal, and he may be more fluent than average when language develops. Yet, contrary to popular belief, there is as yet no evidence that babbling is in any specific way practice for language development. Indeed, the formal properties of babbling and of speech are so different that they suggest somewhat distinct central processes in their production.

Semantic system

Early sentences. An average child uses meaningful utterances by the middle of the second year, and by the middle of the third year babbling virtually disappears in play except as a stylistic device.

At first these utterances vary considerably in both sound and meaning. They may be quite idiosyncratic. Because of the simplicity of the child's phonological system, there may be numerous homonyms if his vocabulary grows rapidly. Meanings are generalized readily, so that a given utterance might on various occasions mean "my coat," "my hat," "my baby carriage," "let's go for a walk," "bye-bye," and so on. Frequently there is a close integration with gesture.

If the first utterances are based on adult words, they may sometimes be very inclusive in reference ("bird") or very narrow ("Bobby"). Adult beliefs about the semantic contrasts needed by children may influence the words they use in talking with children. From the standpoint of adult meanings, the words used by children tend to refer to animal and human movements and to concrete items with characteristic shapes and sizes (Brown 1958). When the child's range of reference of a term is actually tested, it appears to depend on the variety of verbal contexts in which a word is heard and, to a lesser degree, on the variety of physical referents.

Conceptual changes. As the size of vocabulary increases, inevitably there is a change in the conceptual system. The number of semantic contrasts marked by vocabulary grows, and the referential range for each word must therefore narrow. A child might begin by calling all adults "papa," next use the word for his own father, and then later learn the word "adult," which has a similar referential range to the primitive "papa" (Leopold 1939-1949).

In this example, there has been more than a change in range. By the time the word "adult" is present, the child has a hierarchical system of superordinates. The criteria for each class have increased in specificity and changed in character, becoming less visual. Changes in the semantic system have in fact been only sketchily studied. They may include increases in the specificity of terms, increases in knowledge or in concept range as experience grows, a shift from sensorimotor to relational bases for concepts, and shifts in the verbal structure, so that antonyms, synonyms, superordinates, and other structural relations in the vocabulary reflect the critical contrasts employed in the language.

Studies of the deaf and other experimental research have suggested that conceptual development may have important nonverbal roots. Yet words give society a sure way of imposing its conceptual system. Societies differ considerably in the semantic contrasts marked by their vocabulary of kin, color, quantity, shape, time, space, and so on. The sanctions against deviant denotative use of these terms bring the child's comprehension, speech, and presumably his conceptual system into line with his language community.

Verbal relations. The basis of the child's system of relating words shifts by mid-primary school from sounds to meanings and grammatical features. The sound of a word is salient to the preschool child, who readily produces rhymes and alliterative sequences in word play. Words which sound alike are easily confused, leading to contaminations of meaning. On the other hand, children's greater interest in the sounds of words may facilitate the learning of a spelling system or the sound system of a second language. In contrast, adults, who tend to respond less to the sound and who are concerned more with meaning, are known to have greater difficulty with the phonology of a second language, although they may acquire vocabulary far more quickly.

As children mature, their vocabulary increasingly becomes organized in terms of grammatical and semantic replacement classes, and they become more able to isolate words from their situational and sentence contexts. Each word more readily elicits other words. Interpersonal associations are more rapid, more fluent, more specific, and more predictable from the semantic and grammatical system. This high rate of mutual evocation of words may be a help in intelligence tests and in school tasks requiring verbal retention of information. Children vary considerably in their readiness to convert their experience—including nonverbal experience—into spontaneous verbal thought. This skill seems to be a consequence of the verbal milieu in which the child is reared, and hence is responsive to training (see Ervin-Tripp in Hoffman & Hoffman 1966).

Phonology

As soon as a child knows several meaningful utterances it is possible to study his phonological system. The units of this system are phonemes, which are constructs that represent the smallest distinguishable unit of speech and which account for the significant formal contrasts between utterances. A very primitive system is illustrated when

a child has two words, such as "baba" and "tata." At this point there are three phonemes—one vowel and two consonants. Extrapolating from a small number of diary studies, we might expect the following changes to take place: (1) We might next find a system containing four consonant phonemes in which there is a contrast between the stop consonants and continuants. For example, the child might add /m/ and /n/, or /f/ and /s/ to the primitive system. At this point the consonant system would have two intersecting features—place of articulation (front versus back) and type of articulation (stop versus continuant). (2) In the vowels, probably a low versus high contrast will appear first, so the next vowel might be a single higher vowel, followed by a front-back contrast, as in /i/ versus /u/. (3) Typically, a contrast of position is followed by a voicing contrast. When voicing becomes significant, we might find both "dada" and "tata" with different meanings. (4) The consonant system will usually be more elaborate at the beginning of words, so that the number of contrasts may be greater there during the course of development. (5) Syllable repetitions, as in the example, usually decrease in the second year, and the length and variety of word-formation patterns increase. (6) Some sequential arrangements, such as consonant clusters (*ts*, *kr*, *pl*), are absent for a long time, even when the component phonemes are present (see Ervin-Tripp in Hoffman & Hoffman 1966).

This has been a description of the child's phonology in its own terms, but most observers are more likely to notice the mapping of the adult's system onto the child's when the child makes substitutions. Thus, in the above system with three phonemes and a CVCV syllable repetition pattern, any word acquired by the child must become either "tata" or "baba"—an extreme case to be sure. The most obvious substitution patterns are simple replacements, such as the mapping of both stops (*t*, *d*) and affricates (*ch*, *j*) onto stops when there is no stop-affricate contrast. The word formation pattern of the child may require omission of whole syllables or members of clusters. The conversion of "father" into "papa" is predictable for a child who has not yet developed a stop-fricative contrast (between /p/ and /f/), who has a CVCV syllable repetition rule, and who selects the adult stressed syllable.

The child with a simplified phonemic system sometimes has a preferred phonetic realization of a given phoneme and sometimes has random or free variation. In the first case, he might always

say [t] and never use [d] in articulation of "tata." In the latter case, especially common for vowels, he may oscillate unpredictably. A third possibility is that he may use each predictably in a given context. For instance, he may use [d] at the beginning of words and [t] in the middle to realize a single phoneme (Velten 1943).

Although the number of phonemes in children's systems usually is less than in adults', their substitution rules are not always simple and may baffle parents or teachers unfamiliar with phonemic analysis. For instance, some children have a rule making an initial consonant nasal if there is a nasal consonant anywhere in the adult model word, producing imitations like /ni/ for "green." There may be phonemic contrasts in the child's system which are absent in the adult system. Assimilation is very common in children's word-formation patterns, so that neighboring phonemes or successive syllables may influence each other. Yet all of these are orderly rules. The factors producing these idiosyncratic patterns are as yet unknown.

What makes a child's phonemic system change? Perhaps the presence of numerous homonyms encourages change; yet some children tolerate extensive homonymy when they have a large vocabulary combined with a very simple phonemic system and restricted word-formation rules. Understanding or hearing a phonemic distinction is not a sufficient condition for producing it, although each process evidently facilitates the other. Thus, in adults, acoustic discrimination is much sharper when the listeners have learned a corresponding discrete articulation. The teaching of reading and spelling and the alteration of phonology when children learn to speak second dialects and second languages might be much easier if teachers knew more about phonological development [see PERCEPTION, article on SPEECH PERCEPTION].

Grammar

Languages differ considerably in their organization of basic grammatical devices, so it will be necessary to study children's language development in many types of languages to establish well-founded generalizations. For example, in English, the constituent order (e.g., subject-verb-object) has a high degree of regularity; deviations are significant; and the selection of entries in the subject and object position is semantically important. In Russian, on the other hand, there may be much more variability in constituent order, since inflectional suffixes mark the relations indicated by constituent order in English. Children learning both languages

show order regularities before they use markers such as inflection or function words consistently, but children learning highly inflected languages have been reported to learn inflections much earlier (Gvozdev 1961).

Simple syntax. From the very beginning of multiword sentences, children usually reveal order regularities in speech. Certain frequent words may occupy fixed positions. For instance, "where," "there," and "this" may always be in antecedent position, and "up," "on," and "off" in last position. Other words and phrases, such as "broken," "blue," "truck," "the truck," "the broken," then could occupy either position in complement to the fixed items. On the basis of position alone, one can identify primitive word classes and usually a nominal phrase also, which can expand one of the complement classes. From the examples it can be seen that these classes are idiosyncratic and do not correspond exactly to adult classes (Bellugi & Brown 1964).

How do primitive classes develop? They cannot be based simply on imitation, since at this stage children's imitations are at least as simple as their own spontaneous speech, and classes appear even if the adult language has variable order (Gvozdev 1961). They reflect order regularities when they exist in adult language, and in part they reflect semantic features of adult classes (Brown 1958). In their idiosyncratic features they clearly reveal creative and analogizing activity by the child and cannot be based on rote learning. The study of the child's interpretation of what he hears may provide the key to this enigma. But as yet there have been no true experiments on grammatical acquisition in the very young. There is disagreement as to the character of "rules" in children's early grammar and as to the relation between the comprehension system and speech.

Inflections and function words. During the period of simple syntax, English-speaking children employ function words like "the" at random, and as their frequency increases such anomalous sentences may appear as "I see the Mary." The order of mastery of both function words and inflections is influenced by their semantic obviousness.

In English, inflectional suffixes such as plurals are randomly present at first, but in highly inflected languages, such as Russian, often a single form is used before the period of random variation. In many languages there are some irregular inflections, such as "go-went," which are preserved because of their high individual frequency. Children do not usually learn these first, as tense contrasts

at least, even though they are frequent. Among English nouns and verbs, the largest variety of verbs have an inflectional suffix, such as "stop-stopped." It is these forms which are productive or generalized to new words by children. These analogies can be highly resistant to adult influence; typically, a form like "foots" can remain in a child's speech for months after he has learned the plural form.

Sometimes alternative inflections depend upon the preceding phoneme; for example, a plural is formed by "-s" in most cases, but by "-es" in some, as in "mats" versus "matches." Children use the most common form first, then both at random, before discovering the phonemic conditioning rule. During the period of random variation one finds forms such as "handses" and "toasteded" (Ervin-Tripp in Hoffman & Hoffman 1966).

Complex syntax. It is a common observation that children's sentences grow longer as they get older. This is a superficial effect of deeper changes. As we have seen, this increase is due in part to the systematic use of function words and suffixes. Some of the constituents which were optional in the simple grammars—such as verbs—may become obligatory in the more complex phrase structure. Potentially infinite expansions of coordinate and subordinate structures appear. These are all changes in the child's syntax itself; in addition, there may be increases in the amount of information a child can include in a given utterance. One might say that programming capacity increases with age.

In the course of these changes, it is not easy to establish criteria for mastery of the adult syntactic rules. Sometimes a given sentence in a child's speech has the appearance of an adult sentence, but it derives from a different syntax. For example, during the early stages in the development of negation, children commonly use "no" or "don't" as simple negativizing words, much like the plural. Later, as inflection of verbs appears, one may find "he doesn't go." Eventually the child will arrive at the adult rule, which in the negative marks tense and person only in the auxiliary. The intermediate stages of the evolution of the negation rule can be inferred if one has appropriate tests or a sufficiently large text from a child and is willing to make such inferences.

At the age of six, there remain a number of constructions which are still absent in the speech of many children, such as nominalizations of simple verbs (Menyuk 1964). Some of these constructions may be rare in the colloquial speech used to chil-

dren. Perhaps, on the other hand, they involve inherently more complex rules requiring conceptual maturation.

Children's syntactical rules are always inferred from behavior, but the study of comprehension, imitations, spontaneous speech, or other measures may give different results. Comparison of these varying measures may help in the analysis of such inferred processes. Each makes different demands on knowledge, much as recognition and recall make different demands on memory. Imitation, for example, requires phases of perceptions, storage, retrieval, and speech. At different ages imitations are structurally quite dissimilar. At first they appear to be markedly simplified by the child's speech production rules. Later, restrictions occur in the other phases of the process, but eventually the child can perceive and store even the mistakes which he hears (Ervin-Tripp in Hoffman & Hoffman 1966).

Language functions

Private functions. Vocalizing begins as an autogenous activity, and throughout life there exist varieties of speech in which listeners do not actively mediate the speaker's satisfactions. In babies these may include cooing, babbling, and at first, crying. Vocal play with sounds continues into the phase of organized speech. Babies vocalize when they see objects and when they engage in action, but around four and five such speech appears to have an implicit audience. Such monologues, for instance, decrease in isolation, are inhibited by strangers, and increase when difficulties are encountered (Vygotskii 1934). Eventually speech not only is a product of play but aids in its organization, perhaps being a precursor, as Vygotskii believed, of some aspects of covert thought.

Social functions. Social play—for example, in gestural games—may be at least as significant in the evolution of early language as demands for goods and services. Such play receives social rewards, and even a three-month-old infant may vocalize more if so reinforced. It thus becomes difficult to mark any point when one can say that vocalizing becomes intentional. The rhetorical question, ritual naming of objects, and many other vocal performances in the second year appear to be socially motivated and probably vary markedly according to milieu. True offering of information, addressed to lacunae in the listener's knowledge, demands mature social development, and difficulties can still be found in this function during the school years. Because of the heavy dependence of

these different functions on social milieu, it is particularly difficult to establish any generalizations in the absence of experimental research.

Children's speech changes according to the audience, the function, and the setting. The most extreme adaptation occurs in multilingual children, who by three can usually distinguish their languages appropriately. Yet even within a language there may be formal alternations, as in the suffixes "-in" and "-ing" in English, which mark subtle style shifts in the speech of American children.

In many languages there is a special form of speech used in addressing infants, which may be called baby talk, and involves changes in phonology, vocabulary, and syntax. Children may employ baby talk as a stylistic device depending on the listener or the role during play. In languages such as Japanese there may be many changes in syntax or vocabulary according to the age or status of the listener, and these are acquired by children only gradually during the school years. Optional features of syntax, such as use of qualifiers and subordination, may be affected by audience or function. Conversations with adults or expository speech in the schoolroom may draw on syntactic skills not usually employed in conversations with other children.

Schooling. Schooling may indeed mark the most radical change in language functions encountered by children. In the home and among friends the function and form of speech may be quite different—briefer, situationally imbedded, narrative, repetitive, topically limited, aimed at solidarity or aggression. In school, there is a demand for precision, independence from the speech situation, exposition, novelty, breadth of topics, and transmission of information. The latter functions demand more abstract vocabulary and greater use of grammatical structures that signal analytic differentiations. Written language, since it is private, with neither audience nor situational support, is at the farthest remove from the colloquial practice children bring to school (Vygotskii 1934).

Knowledge of language increases, of course, after early childhood. The everyday vernacular of the peer group, not parents, in the preadolescent years remains as our spontaneous adult speech. We acquire new vocabulary from travel, reading, and the acquisition of skills. Later, as our social relationships become more complex we may come to control a greater range of the structural facilities of the language and its stylistic alternatives for such varied purposes as persuasive, expository, and aesthetic discourse. But these changes usually do

not occur in children who lack any secondary education. While it is true that all normal children master the essentials of language before they enter school, variations in the language functions provided by the family and school milieu affect markedly the extent to which children go beyond these essentials.

SPEECH PATHOLOGY

Speech pathology is a branch of communications dealing with disorders of speech and language. Speech pathologists concern themselves with diagnosis, treatment, and prevention of speech and language disorders. Although speech pathology in Europe was once a branch of medicine, today, throughout most of the world, the field has developed as an independent speciality, in somewhat the same fashion that clinical psychology has emerged as an area separate from psychiatry. As is the case with clinical psychology, most training programs in speech pathology in the United States are a part of the graduate program offered by colleges of arts and science. A limited number of training programs are affiliated with colleges of education or colleges of medicine.

Unlike the general field of speech, which is concerned with improving the normal and slightly subnormal, the area of speech pathology focuses on defects of speech and language. Speech is considered to be defective when any one or combination of the following conditions exists: speech is lacking in intelligibility; speech differs so much from normal that it calls undue attention to itself, often with the result that listeners pay more attention to the speech deviations than to what the speaker is saying; speech behavior leads to the development of negative attitudes by the speaker toward his own speech, which in turn often interferes with his over-all adjustment.

Speech and language problems can be described in terms of the acoustic end product perceived by listeners or in terms of the etiology of the problem.

Problems of the acoustic end product

From the standpoint of the acoustic end product, speech and language problems can be considered under five general headings: delayed speech and language, defects of articulation, defects of voice, defects of rhythm, defects of symbolic formulation.

Delayed speech and language. Most normal children are able to speak their first word at approximately age one. Language comprehension and production increase along with articulation ability. By age eight the majority of children have learned to articulate all sounds correctly. Speech pathologists use the term *delayed speech* to describe the speech of children who either do not talk or who

perseverate habits and patterns of infantile speech. If there is vocabulary deficiency, inadequate formulation of ideas, or retarded sentence structure, the term *delayed language* may be employed (Matthews 1957a, pp. 394-395). A well-accepted listing of causes is provided by Van Riper (1963) and includes mental retardation, hearing loss, faulty coordination resulting from disease or paralysis, prolonged illness during infancy, lack of motivation for speech, improper teaching methods employed by parents, confused hand preference, necessity for learning two or more languages simultaneously, shock during the speaking act, emotional conflicts, and aphasia.

The treatment of delayed speech depends upon the significant etiological factors. The child with a hearing loss may need a hearing aid. Other causative factors should be removed or lessened. Van Riper describes therapy procedures for delayed speech. In general these procedures attempt to provide a stimulating environment in which the child is "bombarded" by speech and is taught to associate speech sounds with meaningful people and objects.

Defects of articulation. Defects of articulation in general can be divided into four types: substitution, distortion, omission, and addition. Substitution errors consist of the replacement of one sound with another. A common example is the substitution of *w* for *r*, as in "wed" instead of "red," "twuck" for "truck," and "dwink" for "drink." Other common substitution errors are *w* for *l*, as in "weave" for "leave"; *th* for *s*, as in "thick" for "sick"; and *d* for *th*, as in "dis" for "this."

The second type of articulation error involves sound distortion. This can be observed in the *s* sound when it is faultily produced with a whistling component, nasal air escape, or slushiness. Distortions in the pronunciation of the English *r* are often produced by speakers who have learned English as a second language.

The omission type of articulation error is illustrated by the individual who omits the *r* sound and says "ed abbit" instead of "red rabbit."

The addition type of articulation error is seen in the inclusion of an *r* sound where it is not called for, as in "idear" for "idea."

Articulatory disorders are sometimes classified as functional or organic in terms of possible causal factors. Matthews (1957b) has summarized the literature relating mental retardation and articulation disorders. A frequent cause of articulation disorders is faulty training resulting from inadequate speech environment. If a child's speech model is defective, he is likely to learn defective

speech. (A detailed discussion of etiological factors in functional articulation disorders can be found in Van Riper 1963; Johnson et al. 1948; and Berry & Eisenson 1956.)

Although the majority of articulatory disorders are of functional origin, there are organic factors that can adversely affect articulation. West and his associates (1937) discuss in detail articulation disorders resulting from lesions of the central nervous system. Cleft palate, dental anomalies, structural disorders of the peripheral speech organs, and hearing loss can cause articulation disorders.

Where a structural abnormality contributes to an articulation disorder, the organic defect may need correction prior to speech therapy. Sometimes speech therapy may proceed in conjunction with the correction of the organic disorder. Often, complete correction of the structural anomaly is not possible but speech therapy may prove to be beneficial.

The correction of articulatory errors requires teaching the production and habitual use of sounds. As a rule the sound is taught first in isolation, then in combination with other sounds, and finally in words, sentences, and conversation. Milisen describes a variety of approaches to articulation therapy (Milisen et al. 1954).

Defects of voice. Defects of voice can include complete absence of voice as well as problems of pitch, volume, and quality. Voice may be lacking because of total or partial paralysis or removal of the vocal folds, or the vocal structures may be normal and the absence of voice may be a reflection of a hysterical condition.

Pitch may be inappropriate for the age and sex of the speaker. This would be illustrated by a male talking in an extremely high-pitched voice or a female talking with low pitch. Monotone consists of a sameness of pitch. The failure to vary pitch can not only result in a speech pattern that is dull and uninteresting to listen to; it can also interfere with speech intelligibility, inasmuch as certain aspects of meaning are conveyed by means of variations in pitch.

Just as pitch may be inappropriate, it is possible that volume, also, may be inappropriate. Volume may be so weak that it is difficult for listeners to hear what is being said, or it may be so loud that listeners experience a certain amount of discomfort. Normal speakers do not use exactly the same volume from beginning to end of a message. Just as there are normal variations in pitch, so there are normal variations in volume. The absence of these variations in volume would be considered a type of voice disorder.

The third general type of voice disorder consists of defects in quality. These defects are difficult to describe and should be heard to be fully appreciated. Defects of voice quality sometimes are labeled with such terms as "nasal," "hoarse," "husky," "breathy," "harsh," etc. The quality is considered defective when it is not only unpleasant to listen to but seriously detracts a listener's attention from the message of the speaker.

As is the case with articulatory disorders, there are both functional and organic causes of voice disorder. Imitation of poor speech models, psychological maladjustments, adolescent voice change, poor breathing habits, as well as laryngeal pathology, paralysis, and adenoidal obstructions, appear as causes of voice disorders.

In the case of any type of laryngeal pathology, voice therapy should not be attempted until a medical evaluation and laryngeal examination have been completed. Voice training often includes auditory training, to make the client aware of the differences, in both sound and "feel," between proper and improper use of the voice. Where the voice problem is related to emotional disturbances of any kind, psychological help may be necessary. In those instances where the vocal mechanism has been removed, the client may use an electrical or mechanical vibrator as a substitute for vocal-fold vibration or the client may learn esophageal speech, a technique that involves using air expelled from the esophageal tract as a source of sound vibration.

Defects of rhythm. Defects of rhythm can be described as repetitions, prolongations, or hesitations. Individual sounds, words, or phrases may be involved. Frequently the disruption in rhythm may be accompanied by facial grimaces, tics, or other bodily movements, which in time can become an intimate part of the disruptions of rhythm. Very frequently the disruptions in rhythm and the accompanying grimaces carry with them considerable fear and many negative attitudes on the part of the speaker. The speaker's fear that he will have problems with his speech often contributes to additional difficulties with speech rhythm.

Stuttering. More has been written on the topic of stuttering than on any other single disorder of speech. Matthews (1957a), in a brief summary of theories of stuttering, cites representatives of three broad theoretical viewpoints: (1) dysphemic theories, which suggest that stuttering is related to constitutional abnormality; (2) personality theories, which hold that stuttering is related to psychological maladjustment; and (3) developmental theories, which suggest that stuttering develops largely as the result of environmental conditions.

Therapy approaches are influenced by the thera-

pist's theory concerning the etiology of stuttering. Those who view stuttering in terms of a general neurosis will employ some form of psychotherapy. A therapist who sees stuttering as the result of lack of cerebral dominance will seek ways of establishing a dominant gradient of excitation in the central nervous system. Environmental modification is the goal of many therapists, regardless of the theory of causation of stuttering they subscribe to. Van Riper (1963) not only summarizes much of the literature on etiology and treatment of stuttering but also outlines in detail a therapy approach widely employed in the United States. His therapy seeks to help the stutterer stop reinforcing his stuttering. An important aspect of this therapy consists of eliminating the stutterer's avoidance of feared situations and words.

Defects of symbolic formulation. The defects of symbolic formulation may be of both an expressive and a receptive type. Although defects of symbolic formulation are often categorized as either expressive aphasia or receptive aphasia, in actuality most patients who have difficulty with symbolic formulation have some difficulties in both the expressive and the receptive realm. Individuals with receptive aphasia may be able to hear a speaker say the word "chair" but will not be able to translate the sounds in this word into the concept of a piece of furniture on which a person may sit; they may be able to see and to recognize each of the five letters used in writing the word "chair" but be unable to translate the written letters into the concept of chair. The individual with an expressive type of aphasia may know what a chair is and be able to pronounce all of the sounds in the word "chair" but be unable to put these sounds together so they become a recognizable symbol of the concept "chair."

The treatment of aphasia involves re-education and retraining, which utilizes the past speech background of the patient as much as possible. A detailed discussion of therapy for aphasics can be found in Wepman (1951).

Negative attitudes and frustrations. Often the individual with a speech problem is handicapped by more than just the acoustic end product of his speech. Frequently the speaker's attitude toward his speech constitutes one of his most serious problems. In some instances the speaker may actually talk with a fairly high degree of intelligibility. However, if the speaker's attitude toward his own speech is apprehensive and fearful, he may experience a handicap far beyond what would normally result from the faulty articulation or faulty voice quality alone.

A speech problem not only can interfere with

defective communication in social development but also can lead to the frustration of not being able to make oneself understood and of constantly being made to feel different. Such feelings of frustration, difference, and inferiority can lead to personality problems and attitudes which may be more serious than the original speech problem itself. For this reason, speech pathologists must be interested in the total adjustment of the person who has a speech problem.

Etiology and therapy

If speech problems are examined from the standpoint of etiology, they can be categorized as organic or functional. In actuality it is extremely difficult to fit all speech problems neatly into one or the other of these two broad classifications. The two classifications are presented because they frequently appear in the literature.

Organic and functional factors. Speech problems arising from primarily organic causes would include speech associated with cleft palate, cerebral palsy, dental abnormalities, brain damage, hearing loss, or any other type of anatomical or neurological involvement affecting any of the mechanisms used in speech production.

Etiological factors of a nonorganic type would include lack of stimulation to speak, withdrawal tendencies associated with emotional disturbance, failure to have available good models of speech for imitation, mental retardation, faulty learning, etc. The organic and functional aspects frequently are intertwined. This can be seen in the individual who is aphasic because of brain damage. Because of his aphasia, he experiences considerable frustration. This frustration in turn leads to withdrawal behavior. Frustration and withdrawal behavior contribute to further deterioration of speech. Frequently it becomes difficult to separate the components of the speech problem that are of organic causation from those that represent some sort of functional overlay.

Therapy. The speech pathologist initiates therapy after a thorough diagnosis has been performed. This diagnosis often must include a medical examination, psychological assessment, and determination of hearing acuity. Dental and social-work information are often necessary before an adequate diagnosis can be made. Wherever possible, causative factors are removed or minimized. In the case of cleft palate, for example, surgical or dental procedures may be necessary to provide a mechanism adequate for speech production. In some instances it may be impossible to provide a mechanism that is completely normal. Under these circumstances methods must be found to compensate for the struc-

tural inadequacies. In the case of a severe hearing loss, it may be possible to provide sound amplification in the form of a hearing aid.

Articulatory disorders constitute the largest group of speech problems encountered in children. The majority of articulatory problems are not caused by anatomical, neurological, or other organic factors. Most articulatory problems can be traced to lack of stimulation, poor speech models, faulty learning, and other factors quite far removed from defects of the oral structures. An early step in treatment consists of describing adequately the nature of the speech deviation. The speech pathologist helps the individual with the speech problem to understand the detailed nature of the problem. In some cases this consists of the speech pathologist's helping a client become more aware of his speech errors. A client must learn to distinguish between the correct and incorrect speech productions. A wide variety of procedures will be employed to help the client articulate a sound correctly, to eliminate an undesirable component in voice quality, to produce a pitch level more appropriate to the age and sex of the client, etc. Frequently a client learns to make correct speech productions in isolated sounds or words but finds it difficult to carry over these new patterns into everyday speaking situations. Frequently the newly acquired speech skills result in a pattern of speech that sounds strange to the client. The speech pathologist often spends considerable time helping the client understand his feelings toward his speech problem, as well as his feelings toward the new speech patterns which he acquires. Often the attitude of a parent toward a child and toward the child's speech is a contributing factor. For this reason, speech pathologists frequently spend a good deal of their time in parent-counseling activities.

Because some voice disorders are associated with organic pathology, the speech pathologist may carry out some of his treatment procedures in cooperation with an otolaryngologist. Such collaborative therapy activities may be carried out with psychiatrists, clinical psychologists, plastic surgeons, and dentists, as well as classroom teachers. The speech pathologist cannot limit himself to a consideration of the mechanical aspects of sound production. His interest must be in the person with a speech problem. The modern practice of speech pathology makes comparatively little use of the tongue, lip, and jaw exercises that were prevalent in the field a decade ago.

Training in speech pathology. Standards for the training of speech pathologists have been established by the American Speech and Hearing Association. The association awards a certificate

of clinical competence to individuals who successfully complete the requirements for a master's degree in the field of speech pathology. This graduate program includes didactic classroom instruction, supervised clinic practice, and four years of successful practice, under supervision, in an environment where speech and language problems are diagnosed and treated. Graduate training programs in speech pathology in the United States are accredited by the American Board of Examiners in Speech Pathology and Audiology of the American Speech and Hearing Association. The association is a clearinghouse for information regarding clinical facilities, training institutions, and other data relative to the field of speech pathology.

IV

LANGUAGE AND CULTURE

The key role of language in all human activities has made it perhaps inevitable that the field of linguistics should represent a mingling of several streams of interest. Modern linguistics has arisen from the philological tradition, concerned basically with the classical and modern written languages, and from the anthropological tradition, which has been concerned largely with preliterate peoples. The anthropologist has long recognized the

importance of language, not only as a tool for more effective field work, but as a critical element of the cultural fabric which he studies. Thus we sometimes refer to "anthropological linguistics," which may be defined as the study of previously unknown speech varieties in the context of their cultures; the term contrasts the anthropological approach to language with philological, psychological, or philosophical approaches. Alternatively, we may wish to speak of "linguistic anthropology," focusing attention on language as one element of human culture; the term is analogous to "social anthropology," "economic anthropology," and the like. The older term "ethnolinguistics" may well be used to refer to the same area of interest.

All writers in this field have struggled with the expressions "language and culture" versus "language in culture," both of which are in common use as titles for university courses, scholarly symposia, etc. "Language and culture" seems to imply a dichotomy, which we must then reject in the light of our position that language is *part* of culture. But if we speak of "language in culture," we then lack a separate name for all the other cultural areas whose relationship to language we wish to study. Perhaps the best solution is to give formal recognition to what has most often been done in practice and to use the word "culture" in two ways, on two different levels of a semantic hierarchy. Distinguishing these meanings by subscript numerals, *culture₁*, on the higher level of generality, constitutes learned patterns of human habitual behavior. Language is included along with everything else that contrasts with instinctive behavior. *Culture₂*, on a more specific level, is that part of "*culture₁*," which is *not* verbal communication; in this sense, "culture" contrasts with "language." In most cases, the context of discussion will make it clear whether we are referring to "*culture₁*," or "*culture₂*," just as context normally eliminates confusion between "man;" (opposed to "animal") and "man;" (opposed to "woman").

Taking the view that language is part of culture, linguistic anthropologists have been concerned with these basic questions: In what respects does language fit into the general conception of cultural systems, and in what ways is it distinguished from other components? What similarities are there between the internal structures of language and of other branches of culture? What role does language play in the over-all functioning of culture? In what way do language and culture reflect each other's structure at a given point in time or influence each other over the span of history? What techniques may we use to infer linguistic from

nonlinguistic behavior, or vice versa, either in terms of predicting the future or of reconstructing the past? At this moment, most of these questions still lack definitive answers; the rapid growth of ethnolinguistics, however, suggests that the near future will bring, if not answers to all questions, at least a more unified framework for discussion.

The cultural nature of language. Language is assured a position as a branch of culture by its distinctively patterned nature, by its restriction to the human species, and above all because languages are learned, not transmitted genetically. In spite of the fact that race and language frequently have a historical connection—so that many people who share ancestors also share a common language—such connections are in no way necessary. The nongenetic transmission of languages is vividly demonstrated by the linguistic “melting pot” of the United States, in which people of the most diverse racial backgrounds share common standards of English usage. However, the fact that individual languages are transmitted culturally, not genetically, does not rule out the possibility that mankind has certain unique inborn capacities for linguistic behavior. For some purposes, we may distinguish between *language*, an inherited set of capabilities, and *languages*, particular structures which are built on those capabilities by culture.

The distinctiveness of language. Language obviously stands apart from other communication systems used by humans or animals because of the magnitude of its resources. It is especially impressive to consider that every normal child, by the age of four or five, is capable of using the language of his community to produce a literally infinite number of meaningful utterances. We are far from understanding all of the characteristics of language or of the human nervous system which make this possible. Two things, however, are clearly important—man’s ability to invent *symbols* and the *duality of patterning* in linguistic structure.

If we understand a *sign* to be anything from which the existence of something else may be inferred, then we may define a symbol as a special kind of sign—one with arbitrary, conventionally assigned meaning. Thus, black clouds are a sign of rain, the relationship being intrinsic; but a particular weather flag, as a conventional sign of rain, is a symbol. By the same token, the word “rain” is a symbol; our use of this particular word is conventional and subject to change. Other animals may learn to respond to many arbitrary signals, including words of human language, but it is uniquely human to have the ability to assign arbitrary meaning to signs, i.e., to *invent* symbols.

But language goes beyond other symbolic systems, such as those of gestures, in one very specific feature—the duality of patterning. The meaningful symbols of language—such as words and meaningful parts of words, called *morphemes*—are not indivisible, like a flag or a gesture, but are themselves built up of smaller units. These smaller units are the *phonemes* or sound units of spoken language, and they are meaningless in themselves. Every language uses a small number of these meaningless units—usually less than fifty—to build up a huge number of meaningful units. It is this two-level structuring which gives language a degree of efficiency that is qualitatively superior to, not merely quantitatively different from, other communication systems.

Similarities between language and culture. The identification of such building blocks of language as the phoneme and the morpheme has given linguistics great prestige among the branches of anthropology; it is sometimes said that linguists are the only social scientists to have identified the basic units of their subject matter. The method used in this process of identification is one which moves from the level of observation to the level of structure. First, raw data are classified in terms of a universal taxonomic grid; in studying sound systems, this is the phonetic classification. Then the investigator finds that some phonetic differences, in particular languages, are not associated with contrastive meaning; e.g., the meaning of the Spanish *día* (“day”) is the same whether the initial *d* is pronounced as an occlusive (completely blocking the flow of air with the tongue and then releasing it), or as a fricative (letting air issue continuously between the tongue and the teeth). In every language, however, the linguist also finds that some phonetic differences *are* correlated with differences of meaning; e.g., the difference between occlusive and fricative, although nonsignificant in Spanish, is contrastive in English, serving to distinguish “day” from “they.” The result of such observations is the replacement of phonetic classifications by phonemic classifications, unique for each language. The phoneme is defined simultaneously by the range of noncontrastive sound differences which it subsumes and by the contrasts which it displays with the other phonemes of the system.

This method of qualitative contrast, first applied in phonological study, has been successfully extended to the identification of morphemes, i.e., grammatical units; and many scholars have speculated about their applicability to other areas of culture. The terms *etic* and *emic* have been coined

(after "phonetic" and "phonemic") to refer to the observational and structural levels, respectively, which might be distinguished in such areas as kinship, religion, music, art, and folklore. Such studies are still in their infancy, but they constitute one of the most interesting frontiers of anthropology, based as they are on the assumption that each branch of culture, or indeed culture as a whole, is, like language, an *internally cohesive* system.

The role of language in culture. Language is not merely one of several aspects of culture: it is, at the very least, *prima inter pares*, in that it makes possible the development, the elaboration, the transmission, and (particularly in its written form) the accumulation of culture as a whole. One can imagine handicrafts being taught by one generation to the next without the use of language; but social, legal, religious, political, or economic institutions are another matter. It is hard to imagine that a community of deaf-mutes (if they were deprived of such speech surrogates as writing) could carry on human social life.

But how, exactly, does language (or any other symbolic system) relate to experience? It is commonly said that symbols, like signs in general, "stand for" or "mean" something else. The definition of *meaning* itself clearly cannot be taken for granted. A variety of theoretical models for the concept of meaning, each one valuable for its own ends, has been proposed by philosophers, psychologists, and linguists of various persuasions. The model presented below is not intended to compete with others in defining the "real" nature of meaning, but it may be useful as a framework for ethnolinguistic discussion.

Structural linguists have customarily been extremely cautious in semantic matters, sometimes attempting to exclude them from linguistics altogether. Until very recently, a strictly behaviorist conception of meaning was much in vogue:

We have defined the *meaning* of a linguistic form as the situation in which the speaker utters it and the response which it calls forth in the hearer. . . . The situations which prompt people to utter speech include every object and happening in their universe. In order to give a scientifically accurate definition of meaning for every form of a language, we should have to have a scientifically accurate knowledge of everything in the speaker's world. . . . We can define the names of minerals, for example, in terms of chemistry and mineralogy, as when we say that the ordinary meaning of the English word *salt* is "sodium chloride (NaCl)," . . . but we have no precise way of defining words like *love* or *hate*, which concern situations that have not been accurately classified. . . . (Bloomfield [1933] 1951, p. 139)

These statements seem to imply a model of linguistic function with just two parts—on the one hand, the linguistic form, and on the other hand, the associated nonlinguistic events (and, presumably, contextual linguistic events as well). Thus the definition of the word "salt" would be, at least in part, the actual substance NaCl. But Bloomfield seems to ignore the essentially arbitrary association between the word "salt" and the substance NaCl, in that his model has no place for the human individuals or the human cultures which have chosen this particular linguistic form.

A more satisfactory model was provided some two thousand years ago by the Hindu philosopher Patañjali: "Concentrate separately on the word, the meaning, and the object, which are mixed up in common usage"—which a modern commentator explicates with this example—"When we utter the word 'elephant,' we find that the word, the meaning and the object are mixed up; the word lives in air, the meaning lives in mind, the elephant lives by itself" (Patañjali, *Aphorism* . . .). It is indeed true that the word "lives in the air," in the sense that it is transmitted as vibrations of air molecules. It is equally true that the actual elephant "lives by itself," i.e., exists independently of all human conventions of nomenclature. The only way that these two isolates are related, then, is through the human mind; and we may define meaning not as a "thing," but rather as the *relationship* which associates word and object.

This three-part model is more adequate than Bloomfield's but still does not clarify the relation of language and culture. In order to do so, we may expand the model still further. First, a division may be made between the observational, or *etic*, universe, to which "word" and "object" belong, and the structural, or *emic*, universe, within the human mind. Second, we may distinguish linguistic behavior from its subject matter or content (though

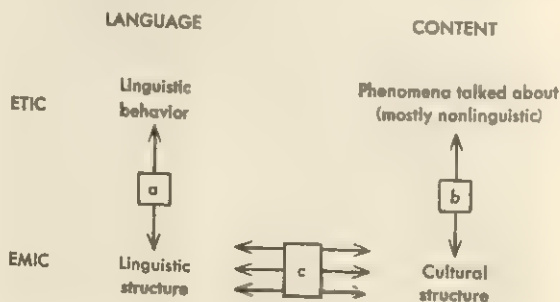

Figure 1 — The relation of language to culture

the subject matter may itself, as a special case, be linguistic behavior, as when linguists talk about language). The two dichotomies then intersect as shown in Figure 1.

In this figure, the arrows marked *a*, *b*, and *c* indicate relationships of importance to the ethnolinguist. Arrow *a* is the relationship which concerns him when he functions purely as a linguist: it may be thought of inductively, in terms of the process by which the investigator sets up a structure to account for his raw behavioral data, or deductively, as the process by which psychological patterns of linguistic competence give rise to observable linguistic performance. Arrow *b* is the analogous relationship that is investigated by the ethnographer: the actual objects and events which concern a particular human group are here linked, by induction or by deduction, to subjective patterns of organization. Finally, the set of arrows marked *c* represents the relationships to which we assign the term "meaning"; this is conceived of not as a direct connection between the utterance "elephant" and the flesh-and-blood *Elephas maximus*, but rather as a connection mediated by "elephant" as an item of the English lexicon and by "the elephant" as an item in the cultural inventory of English speakers.

There are two types of structural units which are linked by the relationships of meaning. The relevant linguistic units are not phonemes or morphemes, but units of a higher level, which are called *lexemes*: these are the minimum units which participate in arbitrary relationships of meaning. Thus, single morphemes like "green" and "house" are lexemes, but so also is the two-morpheme combination "greenhouse" (as opposed to "green house"), since it arbitrarily designates a particular kind of structure. There is still little agreement about structural units of cultural behavior; insofar as they can be identified, they are often called *sememes*. To be sure, there is not always a one-to-one correspondence between lexemes and sememes; people sometimes show culturally determined differences in behavior where their language provides no lexemic differentiation. However, the general regularity of lexeme-sememe correspondences reflects the close integration between language and the rest of culture, and it is in this way that language may be regarded as a key to culture as a whole.

Ethnosemantics. The study of vocabulary as a guide to the way in which members of a culture divide up their universe has received increasing attention, and the relativity of cultural classifications is emphasized with every new empirical

study. Thus, where English vocabulary reflects its users' approach to spatial orientation with the four-way classification "north, south, east, west," the Indian languages of northwestern California reflect the functionally similar but incommensurable division "upriver, downriver, toward the river, away from the river." Anthropologists have begun to pay close attention to such lexemic systems, understanding that they reflect an emic view of the culture being studied, a view uncontaminated by the varying etic frameworks of outside observers. Various terms have been used to identify this study, such as "ethnoscience," "folk taxonomy," "structural semantics," and "ethnosemantics."

A further development in ethnographic semantics is generally known as "componential analysis." This method tries to answer the question, Given a particular set of taxonomic terms used by members of a culture, what are the criteria for applying the individual terms? Taking an example from kinship terminology, if some male collateral kin in generations above ego's are called "uncle" and some are called "cousin," what does one need to know in order to label a particular kinsman correctly? Attempts to answer such questions have resulted in the idea that terms may be conceived of as bundles of simultaneously occurring semantic components. Thus the term "uncle" is applied when the features of "maleness," "ascending generation," and "colineality" are simultaneously present. (A "colineal" in this case is a nonlinear kinsman all of whose ancestors are included in the ancestors of ego.) The term "cousin" is applied in a larger number of cases, but they include those where the features of "maleness," "ascending generation," and "ablineality" are simultaneously present. (An "ablineal" is a consanguineal kinsman who is neither a lineal nor a colineal.) This type of analysis, as applied to kin terms, results in definitions which are both more concise and more exact than the extensional definitions given in traditional ethnographies. Application of componential analysis to areas other than kinship holds great promise.

Language and world view. In addition to correspondences between vocabulary and cultural inventory, a much more controversial type of correlation between language and culture has been proposed. This involves, on one side, whole grammatical systems or subsystems, and, on the other side, whole philosophies or ways of life held to be characteristic of particular cultures (though often not brought to the level of conscious formulation). The interest of anthropologists was drawn to such correlations by Edward Sapir, who not only recognized a linguistic relativity, covarying with cultural

relativity, but also postulated a linguistic determinism operating on culture:

Human beings do not live in the objective world alone, nor alone in the world of social activity as ordinarily understood, but are very much at the mercy of the particular language which has become the medium of expression for their society. . . . The fact of the matter is that the "real world" is to a large extent unconsciously built up on the language habits of the group. No two languages are ever sufficiently similar to be considered as representing the same social reality. The worlds in which different societies live are distinct worlds, not merely the same world with different labels attached. (Sapir [1910-1944] 1949, p. 162)

Benjamin Lee Whorf, a student of Sapir, continued the exploration of the matter, although with less emphasis on the tyranny of language over culture. His position has become known as the "Whorfian hypothesis," which holds that "language patterns [and] cultural norms . . . have grown up together, constantly influencing each other. But in this partnership the nature of the language is the factor that limits free plasticity and rigidifies channels of development in the more autocratic way" (Whorf [1927-1941] 1956, p. 156). The deterministic role of language is easy to understand when we consider how much of culture is transmitted through the linguistic medium. However, the Whorfian hypothesis is easier to accept intuitively than to prove in a rigorous way; in particular, no correlations can be traced between language and world view until specific world views are themselves defined in terms of observable behavior. Whorf shows that Hopi linguistic structure is compatible with a world view involving a peculiar relation between subjective and objective experience; but he tends to assume, rather than to demonstrate, that the Hopi actually hold such a view of the world. Pending the outcome of extensive, strictly controlled, cross-cultural testing of the Whorfian hypothesis, we may limit our acceptance to the following modified formulation: "Insofar as languages differ in the ways they encode objective experience, language users tend to sort out and distinguish experiences differently according to the categories provided by their respective languages. These cognitions will tend to have certain effects on behavior" (Carroll 1963, p. 12).

Language and society. While the studies mentioned above have regarded each language as a unified whole, another type of research has focused attention on the variation that exists within languages or within multilingual speech communities. Such variation, apart from that associated with

geographical dialects or with the idiosyncrasies of individuals, is commonly found to be correlated with one or more socially defined factors, such as the social identity of the speaker, the addressee, or the person referred to, and the social context in which communication takes place. Study of the covariance between linguistic diversity and social structure thus constitutes the new field of sociolinguistics. The findings of this field are applicable, from the synchronic viewpoint, to the diagnosis and analysis of social encounters, and, from the diachronic viewpoint, to examination of the ways in which linguistic patterns and social systems each change under the influence of the other.

LAPLACE, PIERRE SIMON DE

Pierre Simon de Laplace (1749–1827), renowned French mathematician, was born in Beaumont-en-Auge, a village 4 miles west of Pont l'Évêque in Normandy. He was the second of two children of Pierre de Laplace, a syndic of the parish, who owned and farmed a small estate. When Laplace arrived in Paris, barely twenty years old, he had finished his studies and begun his own research. His ability soon impressed d'Alembert, whose disciple he was to become. D'Alembert's patronage secured Laplace a position as a teacher at the École Royale Militaire, where he remained until changes in the organization brought his teaching there to an end. In 1783 he became an artillery inspector (Duveen & Hahn 1957), and in this capacity he made the acquaintance of the young Bonaparte. A mutual respect developed, and from then on Laplace enjoyed Bonaparte's increasingly powerful support. The two became colleagues at the Académie des Sciences; as first consul, Napoleon appointed Laplace minister of the interior, a position he gave up shortly afterward to become chancellor of the Sénat Conservateur. In 1814, however, he turned against Napoleon; he was eventually made a marquis by Louis XVIII, a surprising but not uncommon turn of events in those troubled times.

Laplace achieved distinction not only in mathematics; it was his literary style that won him election to the Académie Française in 1816. His famous sentence on the hidden determinism of natural laws is a good example of his style:

If there were an intelligence that for a given instant could comprehend all the forces that animate nature and the condition of each being that composes it; if, moreover, this intelligence were sufficiently great to submit these data to analysis, it would create a single formula that would embrace both the movements of the vastest bodies of the universe and those of the smallest atoms: to this intelligence nothing would be uncertain, and the future, as the past, would be present to its eyes. ([1814] 1951, p. 4)

Although Laplace's work has literary elegance, his demonstrations are not always rigorous; often they are even obscure. He frequently wrote "it is clear that . . ." in place of long and difficult calculations.

Laplace presided over the famous Société d'Arcueil, one of the informal scientific societies that flourished in the nineteenth century. It took its name from Laplace's estate, where he and the great chemist Claude Louis Berthollet periodically re-

ceived their students to discuss scientific questions in an informal atmosphere.

Although our primary concern here is with Laplace's contributions to probability and statistics, it is worth noting that the full scope of his work includes physics (the theory of capillary phenomena, the exact formula for the speed of sound), pure mathematics, and celestial mechanics (he was dubbed a "second Newton"). In probability and its applications Laplace systematized and further extended the scattered researches of his predecessors, bringing the subject to full flower in the third edition (1820) of his great treatise, *Théorie analytique des probabilités* (1812). This is why Todhunter wrote: "On the whole, the Theory of Probability is more indebted to him than to any other mathematician" ([1865] 1949, p. 464).

Laplace was not content to make important discoveries; he also thought it necessary to communicate them to a wide public. To this end he wrote two popular works addressed to the intelligent and educated general reader, *Exposition du système du monde* (1796) and *Essai philosophique sur les probabilités* (1814). Other French mathematicians have continued this practice; thus, Émile Borel thought it useful to write an analogous work, *Le hasard* (1914), which took into consideration the progress made since Laplace.

Generating functions and characteristic functions. Motivated by problems arising, for instance, in the mathematical treatment of games of chance, Laplace, in the epochal *Mémoire sur les suites* (1782), developed the general theory of a powerful power-series technique for solving finite-difference equations, or recurrence relations, which he termed the "method of generating functions" (*calcul des fonctions génératrices*; *ibid.*, p. 1). In Book 1, Part 1, of his *Théorie analytique des probabilités* (1812) he reproduced this *Mémoire* almost entirely, and in Book 2 he made repeated use of generating functions in solving a great variety of probability problems arising in the mathematical treatment of games of chance. The probability-generating function of a random variable, X —that is, the mean (or expected) value of t^X , where t is a "dummy" real variable—had already been used (without being named) by De Moivre, in studies of games of chance (1730, pp. 191–197; [1718] 1756, pp. 41–43), and by Simpson and Lagrange, in their studies of the distribution of the arithmetic mean of independent observations under various laws of error (Simpson 1756; 1757; Lagrange 1770–1773). However, it is Laplace's extensive discussion of generating functions (1782)

and the applications of them in his *Théorie analytique des probabilités* that is the actual source of their widespread use in probability theory, combinatory analysis, and the solution of finite-difference equations and recurrence formulas (see David & Barton 1962; Feller 1950; Fréchet 1940–1943; Jordan 1939; Riordan 1958; Uspensky 1937). The invention of the characteristic function (*fonction caractéristique*) of the distribution of a random variable X (that is, the expected value of e^{itX} , where $i = \sqrt{-1}$) and the associated inversion formula for deducing the distribution function of a random variable from its characteristic function are often attributed to later writers, such as A. L. Cauchy, 1789–1857, and Henri Poincaré, 1854–1912. Laplace, however, introduced this very same (characteristic) function, without assigning it a name, and gave the associated inversion formula for the case of a discrete random variable, in article 21 of Book 1 of his *Théorie analytique des probabilités* (it also appears in *Oeuvres complètes*, vol. 7, pp. 83–84) and then employed such functions systematically in Book 2, Chapter 4 (cf. Molina 1930, arts. 3–4). The technical advantages possessed by the characteristic function permit simplification of many manipulations and proofs, although when X takes only integral values the generating function is usually adequate. [See PROBABILITY, article on FORMAL PROBABILITY.]

Bayesian inference. Laplace was apparently the first to have stated in a general form what is now called Bayes' theorem (*Théorie analytique* [1812] 1820, book 2, art. 1; Molina 1930, appendix I). Several scholars have deprecated Laplace's originality in this area of "probability of causes," or Bayesian inference. [See BAYESIAN INFERENCE for a discussion of the probability of causes.] But Laplace did introduce an essential innovation here. Bayes had considered only the case where the a priori probabilities are equal (as an evident hypothesis when one is ignorant of these probabilities); Laplace extended Bayes' theorem to cover the general case where these a priori probabilities are not necessarily equal. What has generally not been stressed enough is that Bayes' theorem—whether generalized or not—is really only an interpretation of a standard relationship for conditional probabilities. [See PROBABILITY, article on FORMAL PROBABILITY.] It is the interpretation of the formula itself that is important here. A discussion by Molina (1930) clearly establishes Laplace's position and demonstrates previous misunderstandings of it.

Normal distribution. Laplace should have the major credit for discovering and demonstrating the

central role of the normal distribution in the mathematical theory of probability and for determining its principal mathematical properties [see DISTRIBUTIONS, STATISTICAL, article on SPECIAL CONTINUOUS DISTRIBUTIONS].

De Moivre in 1733 had shown how to employ integrals of the function $\exp(-t^2)$ to approximate sums of successive terms of the binomial expansion of $(a + b)^n$ when n is large, obtaining what we today call the normal approximation to the binomial probability distribution [see DISTRIBUTIONS, STATISTICAL, article on APPROXIMATIONS TO DISTRIBUTIONS]. (De Moivre's analysis is readily available in Smith [1929] 1959, pp. 566–575.) Laplace extended this approach in two important directions.

Approximations to the normal integral. He developed (1781) a general method for approximating an arbitrary definite integral by a series expansion in terms of integrals of the function $\exp(-t^2)$ and its derivatives, anticipating by a century the so-called Gram–Charlier Type A series expansion. He then utilized this technique to approximate various discrete and continuous probability distributions arising in games of chance and other problems in the calculus of probabilities. Remarking (1786a, p. 305) that the integral of $\exp(-t^2)$ arises so frequently that it would be useful to have a table of its values for a succession of limits of integration, Laplace provided (1785, sec. VI; 1805; [1812] 1820, book 1, art. 27) the now well-known power-series, asymptotic-series, and continued fraction expansions for integrals of the function $\exp(-t^2)$. These many results collectively constitute Laplace's first great contribution to the central role of the normal distribution today, and throughout their development the function $\exp(-t^2)$ seems to have been regarded exclusively as an approximating function—neither De Moivre nor Laplace appears to have regarded it or any corresponding expression as a law of error or even as a probability distribution in its own right.

Central limit theorem. Laplace's second great contribution to the establishment of the leading role of the normal distribution is his discovery and proof of what we today call the (classical) central limit theorem. De Moivre's result of 1733 is a special case of this theorem, as are many of Laplace's results in his papers of 1781, 1785, and 1786, but the theorem itself appears for the first time in the important *Mémoire* (1810, sec. VI), for the case of n independent errors from a common arbitrary symmetric discrete distribution on the interval $(-a, +a)$. Then (*ibid.*, sec. VI), by considering the discrete distribution corresponding to a fine subdivision of his double exponential law of error

(1774, sec. v), $\frac{1}{2}m \exp(-m|x|)$, he illustrated the extension of this important theorem to symmetric continuous distributions on the interval $(-\infty, +\infty)$. Gauss (1809, arts. 175–177) had deduced his law of error, $C \exp(-h^2x^2)$, and thence his development of the method of least squares, from the principle of the arithmetic mean. Laplace's central limit theorem provided an alternative justification, or "proof," of this law of error as the limit of the distribution of the sum of n independent random errors as $n \rightarrow \infty$ when the relative contribution of each to their sum tends to 0 as n increases, and thus he provided a valid basis for the method of least squares when the individual results involved "are each determined by a very large number of observations, whatever be the laws of facility of the errors of these observations," and hence "a reason for employing it in all cases" (1810, supplement, p. 353). [See DISTRIBUTIONS, STATISTICAL, article on SPECIAL CONTINUOUS DISTRIBUTIONS; see also LINEAR HYPOTHESES, article on REGRESSION.]

Laplace's proof had only the limited precision current in his time, but it was later made more rigorous and more general by Aleksandr Mikhailovich Liapunov, Paul Lévy, and others. Laplace's demonstration centers on the hypothesis that one deals with the *sum* of independent random variables, but in applications neither independence nor summation may be appropriate. Other functions of random variables can lead to other distributions; for example, if instead of a sum one deals with the greatest random variable, entirely different limit distributions can result (Fréchet 1927). One of these distributions has found application in flood protection, breaking strength of materials, and other areas (Gumbel 1958).

Estimation. Laplace's writings contain the seeds of ideas that have been carefully studied only in recent years: optimum point estimation, hypothesis testing, and confidence interval estimation. Laplace proposed (see 1774, sec. v) that when estimating a parameter, θ , one use that function $T = T(Y_1, Y_2, \dots)$ of the observations Y_1, Y_2, \dots for which the mean (or expected) absolute error of estimation, $E|T - \theta|$, is a minimum for the given probability distribution of errors. For the case of three independent identically distributed observations he gave an explicit algorithm for finding such a function to use for estimating the location parameter of their common distribution, $f(y - \theta)$, when this is completely specified except for the value of θ . He subsequently extended (1781, sec. xxx) this procedure (which is the same as Pitman's method of "close estimation"—see Pitman 1939) to cover n independent observations in the

one-parameter case. Gauss's reformulation (1821) of the method of least squares in terms of minimum mean-square error of estimation (i.e., $\min E[(T - \theta)^2]$) stems directly from this earlier work of Laplace's.

Many modern statisticians see the problem of confidence intervals as one of providing a random interval that contains, with at least a specified probability, some parameter of the distribution sampled. Laplace, however, gave another—somewhat vague—interpretation of the interval (*Oeuvres complètes*, vol. 7, pp. 286–287). Major differences of opinion persist about the interpretation of such intervals. [See BAYESIAN INFERENCE; ESTIMATION, article on CONFIDENCE INTERVALS AND REGIONS; FIDUCIAL INFERENCE.]

Applications to demography. Laplace was not satisfied merely to describe useful statistical methods; he never stopped applying them, most particularly to demography. In this area he was preceded by the great naturalist Buffon, whose early career was in mathematics, although this is not generally known, and who solved the famous problem of the needle thrown onto a table covered with parallel lines. His "Essai d'arithmétique morale" of 1777 deals with demographic statistics; he notes, for example, the propensity that most people have to use round numbers in stating their age. Laplace, using more general and more precise mathematical methods and ideas, was able to treat demographic problems much more intensively. Buffon had already noted the general preponderance of male over female births; Laplace noted that during the years 1745–1785, 393,386 boys and 377,555 girls were born in Paris, and he proved that given certain natural hypotheses, the probability that the chance of a male birth would be more than $\frac{1}{2}$ is $1 - 1/N$; in this example N is a very large number, greater than 10^{72} . In an anomalous case cited by Buffon—the birth of 203 boys and 213 girls in the village of Vitteaux over a five-year period—the same probability is only about $\frac{1}{2}$. Laplace pointed out that there is no logical contradiction between the two cases, since it is only for large populations that the value of the sought probability is near unity—i.e., that the event is almost certain.

An exact census of the French population would have been a very difficult undertaking in Laplace's time, and he therefore tried to estimate the population indirectly, by a rather curious method. He used in the approximation the rough constancy of the ratio between total population and annual number of births, so that if the numerical value of the ratio is known, one need only multiply it by the number of births to obtain an estimate of the

population. The government accepted his proposal that studies be made to determine annual births and total population for thirty *départements*, selecting in each *département* only those parishes whose mayors seemed sufficiently conscientious. On September 22, 1802 (the Republic's New Year's Day), the inhabitants of these parishes were counted, and the number of births in each of the three preceding years was also recorded. From the resulting ratio and an estimate of the total number of yearly births in France, Laplace estimated the population to be 25 million.

Laplace was also interested in statistics having to do with the duration of marriages and with life insurance. In addition, he studied the application of statistics to problems of social order, such as the validity of trial evidence and of court judgments, and the concept of "moral expectation." This concept, introduced by Daniel Bernoulli, is based on the observation that the richer a man is, the less concerned he is about any fixed moderate sum of money. Laplace added to this generalization the qualification "all other things being equal," meaning that the benefit to be calculated depends in general on an infinity of circumstances that are impossible to evaluate and that are relative to the individual who is calculating it [see UTILITY]. The work that Laplace did on trial evidence and court judgments has been especially controversial; J. L. F. Bertrand, in his caustic way, treated it with complete disdain, but Borel ([1914] 1948, pp. 251-262) felt that Bertrand was too harsh.

LASHLEY, KARL S.

Karl Spencer Lashley (1890-1958), American psychologist, was born in Davis, West Virginia, of middle-class English stock. His father, Charles Gilpin Lashley, was the manager of the family store in Davis and the founder of a small bank there; at various times he served in such political posts as mayor and postmaster. Lashley's mother, Maggie Blanche Spencer, was descended from Jonathan Edwards, the philosopher, theologian, and educator of American revolutionary times; she had been a country schoolteacher before her marriage. After that she continued to be an avid reader, amassing a personal library of more than 2,000 volumes, and was an informal "adult education" instructor in diverse subjects. She appears to have been responsible for cultivating Lashley's love of nature and of learning.

Except for four years, from 1894 to 1898, during which the family, afflicted with "gold fever," trekked to the west coast and Alaska, Lashley spent his early years in Davis. He showed signs of being a prodigy. During his elementary school years, his interest in nature and animal behavior was already evident in his collection of all sorts of plants and animals, including many pets. During this period, too, his marked mechanical aptitude became apparent; he expertly designed many gadgets, small and large, and made them in his own workshop.

Graduating from Davis High School at the age of 14, he entered the University of West Virginia, but because his high school was unaccredited he had to spend a year in preparatory work before becoming a freshman. Although vaguely inclined toward engineering, he enrolled, at his mother's wish, in a liberal arts program, intending to major in Latin or English. It was only to fill an unscheduled hour that he enrolled in a course in zoology taught by John Black Johnston (later dean at the University of Minnesota when Lashley taught

there). This contact with Johnston crystallized his interest in zoology for, as he later wrote, "Within a few weeks in this class I knew that I had found my life's work" (Beach 1961).

After Lashley's freshman year Johnston left and was succeeded by Albert M. Reese, who appointed Lashley departmental assistant. In this role he found a fascinating Golgi series of frog brain sections and proposed to "draw all the connections between the cells." To his surprise, most of the cells were not stained and therefore not visible. He later commented, "... I think almost ever since I have been trying to trace those connections" (*ibid.*, p. 169). Lashley went on to take all the courses offered by Reese, the only zoologist on the faculty, but he got much of his education in zoology by independently working out projects for which Reese gave only the briefest instructions. Lashley's philosophy of education and handling of his own students reflected this experience with independent work.

In 1910, with a B.A. in zoology, Lashley went to work on a master's degree at the University of Pittsburgh, where he had been awarded a teaching fellowship in biology. It was here that he took his only formal course in psychology. This was a laboratory course in experimental psychology taught by Karl Dallenbach who later wrote, "Lashley was intensely interested and was the outstanding student in the class. . . . He showed in that course the promise that he later fulfilled" (*ibid.*, p. 170).

Lashley received his master's degree in June 1911 and went that summer to Cold Spring Harbor to do research on the variability in the number of cirri in the ciliate *Stylonychia*. (Cold Spring Harbor is a prominent Long Island center for biological research; during the summer months many outstanding academic biologists work there.) This research led to his appointment by H. S. Jennings as a teaching fellow in zoology at Johns Hopkins University. There Lashley worked with Jennings on paramecia and with S. O. Mast on the behavior of various invertebrates, taking his Ph.D. in 1914 with a dissertation on inheritance in asexual reproduction of *Hydra*. During this period he also pursued his interest in psychology, working with Adolph Meyer, professor of psychiatry and director of the newly established Phipps Clinic, and with John B. Watson, then professor of psychology.

Watson's behavioristic approach had tremendous appeal for Lashley and led him to do postdoctoral work on vertebrate behavior. This work extended over three years, from 1914 to 1917, during which he slowly formulated and launched the rich program of research and writing he was to carry on

for the rest of his life. The first two years he held successive appointments in zoology as Bruce fellow and Johnston scholar but worked with Watson on a variety of problems: field experiments on reproductive behavior of terns (in the Dry Tortugas), acquisition of human motor skills, color vision in birds, conditioning of the salivary reflex, and effects of strychnine and other drugs on maze learning in rats.

While pursuing these experiments, Lashley became interested in the work of Shepard Ivory Franz, who was examining the behavior of brain-injured patients at Saint Elizabeths Hospital in Washington, D.C. Franz was also inaugurating work on the behavioral effects of experimental brain lesions in animals. After frequent journeys to Washington to observe this work, Lashley was permitted to study neurological cases in the wards and to acquire the necessary surgical and histological skills for performing studies of the neural basis of learning. Here he got started solidly on the research career that eventually brought him eminence and recognition.

By the fall of 1917 the United States had entered World War I, and many psychologists were in the army or heavily involved in war-related activities, but Lashley's vision was too poor to meet army standards. Therefore, when he had completed his period of postdoctoral training, he accepted a post at the University of Minnesota arranged by Robert M. Yerkes, who was slated to become chairman there at the war's end but never did. Morale in the department was not high, and after one year Lashley, taking a leave of absence, accepted a position with the U.S. International Hygiene Board. Although he was working once again with Watson, this time in a program dealing with public education on the dangers of venereal disease, this assignment was not a productive one, and in 1920 R. M. Elliott, the new chairman of the department of psychology, prevailed on Lashley to return to the University of Minnesota as assistant professor.

Lashley's intellectual pre-eminence and prolific research on brain function brought him rapid promotion: in 1924, at the age of 34, he was made a full professor. In 1926 he left Minnesota for Chicago, at first serving as research psychologist with the Behavior Research Fund at the Institute for Juvenile Research and later, in 1929, moving to a professorship at the University of Chicago. In 1935 he went to Harvard University as professor and in 1937 was made a research professor in neuropsychology, a title he held until his retirement in 1955. However, in 1942, in a joint arrangement with Yale University and certain private founda-

tions, he moved to Florida as director of the Yerkes Laboratories of Primate Biology.

It has been said of Lashley that he was an "inspiring teacher who described all teaching as useless" (Beach 1961, p. 163). He himself frequently asserted that "those who need to be taught can't learn, and those who can learn don't need to be taught" (*ibid.*, p. 182). He applied this principle by eschewing formal teaching, often raising artificial barriers to registration in his courses. Because his research was so excellent, he managed better than any other academic psychologist of his time to stay out of the classroom. The few lectures he did give were usually stimulating, often exciting. And in seminars he had few peers; he was an impressive scholar, with a pleasant wit and a fascinating intellect. Like Mark Hopkins, however, he was at his best "on a log." He was always available to graduate students and postdoctoral fellows in his laboratory, and for scores of psychologists their informal contacts with Lashley were to be the most significant periods of their education. In this way Lashley was a great teacher even though fewer students, probably, have studied under him formally than under any other psychologist of distinction.

One other related characteristic of Lashley's deserves mention. This was his "go-it-alone" attitude toward research. He had fewer collaborators and published fewer joint papers than most other comparable scientists. Except for very routine work, he did all his own research, "running" his animals, doing data analysis, making histological reconstructions, and writing his own papers. He expected the same of others working with him. He never directed but only advised when his advice was asked. He felt strongly that research of quality must be carried out by scientists of quality, not by a host of assistants and graduate students. It is easy, therefore, to understand his dismay at the increasingly large amounts of money being employed in organized research. Writing in 1953 to Watson, Lashley said, "The money available for research now is rather shocking. The man who doesn't have \$20,000 per year for research is probably intellectually honest. There are not enough competent men to spend the money" (*ibid.*, p. 180).

Work on brain function. Lashley's most productive phase was launched in his work with Franz. At first he merely took for granted the connectionism of Watsonian behaviorism and looked for the neural basis of the connections. This, however, proved elusive, for in study after study in the 1920s he obtained data suggesting a field theory rather than a connectionist theory of brain function.

Lashley's reasoning and his findings in these studies should be briefly summarized. Connectionist theory holds that complex behavior is made up of conditioned reflexes, each forming a connection through the conditioning process. The connection, Lashley reasoned, should have a definite locus in the brain just as a connection in a telephone system does; he, therefore, tried to find a definite localization of these connections. His basic technique was to train an animal to run a maze or make a discrimination both before and after he had made lesions of different sizes in various areas of the cerebral cortex. He then tested for such effects of the lesion as a deficit in retention or learning ability. Except for certain specific visual discriminations discussed below, he found no localization of function. Deficits were found, indeed, but they were not specific to any particular cortical areas. Instead, the degree of deficit depended on the amount of cortex removed rather than upon its locus.

W. S. Hunter and others argued that Lashley's reasoning was faulty, and the present author agrees. Hunter pointed out that mazes involve many different cues, as others had shown by depriving animals of various senses, and complex motor responses. Quite specific localization of connections in the brain could well exist, but so many different connections would be involved in a habit like maze running that one could statistically expect the results Lashley obtained. Lashley's experiments, therefore, were not crucial to the issue. But Lashley felt otherwise and believed that his experiments did disprove the existence of specific connections and required explanation in terms of field-theory concepts.

Thus, Lashley came to propose two concepts (or principles) for which he became widely known and which had considerable influence on subsequent research. The two concepts were *mass action* and *equipotentiality*. Both were presented in his 1929 monograph *Brain Mechanisms and Intelligence*. By mass action he referred to his finding that learning, or at least certain kinds of learning, is mediated by the cerebral cortex as a whole. This principle is based mainly on his studies of maze learning which showed that the efficiency of learning depends roughly on the amount of cortex present and not on any particular cortical locus.

The related concept of equipotentiality came out of his studies of vision and applies primarily to sensory systems. It refers to the ability of certain parts of a system to assume the functions of its other parts. Lashley had found, for example, that a rat can relearn a visual discrimination after the

discrimination has been destroyed by a lesion of the visual cortex; also, a rat can discriminate visual stimuli perfectly when only a small remnant of its visual cortex remains intact. From such results he concluded that various parts of a system are "equipotential" for the mediation of a learned visual discrimination.

Other investigators have, of course, pursued the problems raised by Lashley's work and his interpretations. Using more sophisticated physiological and behavioral techniques than Lashley had at his disposal and giving more attention to the brain of the primate, they have found more localization of function than the principle of mass action would lead one to expect. Indeed, in the primate brain there is considerable localization of learned functions. Still, Lashley was largely correct. The localization is far from precise, and within large areas of localized function there are mass-action effects. As for equipotentiality, later investigations bear out the presence of this phenomenon within sensory systems. It is the interpretation rather than the fact that is in question, and there are now complex alternative explanations available. The problem, however, remains far from solved and is in nearly the same state as Lashley left it.

Work on sensory functions. In another major phase of Lashley's work, the study of sensory functions, he made considerable contributions to the study of the generalization of learned visual discriminations, much of the work being planned as tests of connectionist versus field theories. He also made contributions to neuroanatomy. Concentrating at first on the visual system, he traced neural connections between the retina and the lateral geniculate nucleus of the thalamus and between this nucleus and the cerebral cortex. Later he extended this kind of neuroanatomic analysis to other sensory systems. His papers on thalamocortical connections (1941) and on the microscopic structure of the cortex are classics in their fields. In them he showed that although there are point-to-point projections in sensory systems, these systems cannot be rigidly compartmentalized. Later work, with more refined techniques, has borne him out.

Work on neural functions. The final major aspect of Lashley's work was an attempt to construct a general theory of neural function. Here he was frustrated; his grand design was to develop a theory of how the brain works in perception and learning. Having held earlier that other simple theories were untenable, he now turned to various forms of field theory. Many of his experiments and, particularly, his later papers were concerned with tests of such theories. In the end he felt he had succeeded only in exploding the theories

proposed but not in devising one that would satisfactorily stand the test of experiment. He had to be content with the thought that he and his generation had only laid the groundwork for building a good theory at a later date. Despite his frustration in theory building, however, he adhered steadfastly to the belief that a satisfactory theory would some day be possible. In his last published article, "Cerebral Organization and Behavior," he made an impressive case for his claim that the study of "the organization [of] mental states does not reveal any operations which cannot be accounted for in principle by the mechanism of the brain" (1958, p. 15).

Not long after this was written, Lashley collapsed and died in Poitiers, France. He left over 100 papers of an experimental or theoretical nature, but no book—because he could never make a large-scale theory stand up. Without question, he was the twentieth-century pioneer in the experimental study of brain functions and behavior.

LASKI, HAROLD J.

Harold Joseph Laski (1893-1950), teacher, political scientist, and British Labour party leader, was born in Manchester, England, the second son of Nathan and Sarah Laski; his father was a

prosperous cotton shipper, a prominent Liberal, and a leader of the orthodox Jewish community. The young Laski's intellectual gifts and his precocity were demonstrated by an article he wrote when he was 16 years old and still a student at the Manchester Grammar School. The article, "On the Scope of Eugenics," which appeared in the *Westminster Review* in July 1910, called forth a letter of congratulation from Sir Francis Galton. For six months after he left school, Laski pursued his interest in eugenics by studying with Karl Pearson at University College in London.

In the summer of 1911 he broke with his family by marrying a Gentile, Frida Kerry, who was eight years older than he, and in the fall of that year he began his undergraduate studies at New College, Oxford. After a year of reading science, he shifted to history; he studied under H. A. L. Fisher and Ernest Barker and was strongly influenced by the writings of F. W. Maitland. During his undergraduate days, Laski was active in the women's suffrage movement, in which his wife was deeply interested. In this connection he became a close friend of H. W. Nevinnson and George Lansbury, then editor of the Labour newspaper, the *Daily Herald*. After receiving his degree in 1914, Laski spent the summer months writing articles for the *Herald* on Ireland and on constitutional issues that affected labor. When his attempt to enlist in the armed forces ended in medical rejection, he accepted a post as lecturer in history at McGill University in Montreal, Canada. While at McGill, he wrote his first book, *Studies in the Problem of Sovereignty* (1917).

Two years later, in 1916, as a result of a meeting with Felix Frankfurter, who became a lifelong friend, Laski accepted a post as instructor in history at Harvard University. For the next four years, Laski was a stimulating teacher and a lively member of the Harvard intellectual community. He wrote several books during this period, including *Authority in the Modern State* (1919) and *The Foundations of Sovereignty, and Other Essays* (1921); in these works he argued against the myth of the sovereign, omniscient state and defended the doctrine of political pluralism in a series of historical and analytical essays. The state, he maintained, is not the supreme association to whose will all other groups must bow, but is only one among many groups—corporations, unions, churches, societies of all kinds—with which it is engaged in a constant struggle for men's loyalty and obedience. Laski's pluralistic view of the state reflected the influence of Gierke, Maitland, and Figgis, as well as the antistatist and anti-idealist currents in political thought and action that were

strong before and after World War I. Even at this period, Laski's primary concern was with the freedom of workers' organizations from control by the "sovereign state," and in October 1919, he gave striking evidence of this concern by a public defense of the Boston policemen who were then engaged in a strike that had outraged the leaders of the community [see PLURALISM].

In 1920 Laski left Harvard and his many American friends, chief among whom was, perhaps, Justice Oliver Wendell Holmes, with whom he maintained close touch until Holmes's death. Laski accepted a post at the London School of Economics and Political Science, where, in 1926, he succeeded Graham Wallas as professor of political science. Laski taught at the School until his death 24 years later; he was so well known and so influential among students that his name and the London School became almost synonymous terms in the minds of many people, especially of students from America and from Asia and Africa.

After his return to England, Laski became increasingly involved in politics and political discussions and in writing for the *Nation*. He was active in the election campaign of December 1923, which led to the first Labour minority government. Yet he found time for the teaching and counseling of students and for writing his most comprehensive study of politics, *A Grammar of Politics* (1925). In this work he moved away from his earlier pluralism and adopted a position that might be called "socialized Benthamism." He now accepted the view he had previously rejected, that the state was "the fundamental instrument of society," and he argued that its purpose was to "satisfy, or organize the satisfaction of, the wants of men on the largest possible scale." Yet he indicated that he retained a good deal of suspicion of political power by advocating a large measure of decentralization, consultation with organized groups, and restraints on governmental action. This suspicion of state power reflected his belief that in practice its incidence was heavily weighted in favor of the interests of the wealthy and powerful members of society. Laski, now committed to a democratic or Fabian socialism, urged that political democracy was virtually meaningless unless it led forward to "economic democracy" or socialism [see ECONOMIC THOUGHT, article on SOCIALIST THOUGHT].

From 1925 on, he began to express doubts that the necessary major reforms of the economic and social systems could be attained by the methods of political democracy. In his book *Communism* (1927), for example, he argued that since the workers no longer accepted capitalism or regarded

it as legitimate, the only alternative to revolution was a series of major concessions by the ruling class—acceptance of nationalization of essential industries, sharp curtailment of inheritance rights, comprehensive regulation of private business, and guarantees of adequate wages, working conditions, and educational and welfare opportunities. He was not optimistic about the willingness of capitalists to accept these moves toward a more equal society and to abdicate from power peacefully, and in *Liberty in the Modern State* (1930) he warned that the price of social conflict is always the destruction of freedom.

With the advent of the great depression, the rise of fascism in Europe, the collapse of the British Labour government in 1931, and the defection of Ramsay MacDonald, Philip Snowden, and James H. Thomas from the party, which left it leaderless and bewildered, Laski's hopes for a peaceful and gradual transition to socialism grew dim, and his doubts about the possibility of achieving socialism by constitutional and democratic means became much more intense. In a series of works written during the 1930s, such as *Democracy in Crisis* (1933), *The State in Theory and Practice* (1935), *The Rise of European Liberalism* (1936), and *Parliamentary Government in England* (1938), he abandoned his Fabianism in favor of the Marxist view that the contradictions of capitalism were insoluble and that a democratic political system was incompatible with a capitalism in crisis. On the basis of British, French, German, and Italian experience, Laski now argued that once the operations of political democracy threatened the continued existence of capitalism and interfered with the pursuit of profits, the ruling class would destroy democracy and the labor movement and would initiate an authoritarian regime. The liberal and socialist alternatives to the communist doctrine of the necessity of violent revolution would then become untenable, and revolutionary socialism and fascism (the political form of capitalism in decay) would thus be left as the only serious contenders for power.

These were the years of Laski's most intense involvement in politics. From 1937 to 1949 he was a member of the National Executive of the Labour party, where he was often critical of the moderate views and tactics of the party's leaders. During the late 1930s his public influence probably reached its high point, this was the period of the Left Book Club, directed by Victor Gollancz, John Strachey, and Laski. During the Spanish Civil War he joined such left-wing Labourites as Sir Stafford Cripps and Aneurin Bevan in the Unity

Campaign and the popular front movement of all antifascist groups, which was condemned by the Labour party leaders and by the party conference in 1937.

From the fall of 1938 to the end of the summer of 1939 Laski was in the United States, where he taught at the University of Washington and delivered at Indiana University the lectures that were later published as *The American Presidency* (1940). Shortly after his return to England the war began. The London School of Economics was evacuated to Cambridge, and during the war years Laski divided his time between teaching, assisting Clement Attlee after he became deputy prime minister under Churchill in 1940, and traveling around the country to address Labour party meetings and give lectures at military camps. Although overwork led to a serious nervous breakdown in 1943, he soon resumed his many activities and his writing. His major wartime publications were *Reflections on the Revolution of Our Time* (1943) and *Faith, Reason, and Civilization* (1944); in these books, and in many articles and speeches, he urged the leaders of the Labour party to insist that the Churchill coalition government commit itself during the war to a program of major social and economic reforms that would be carried out when peace was restored. In the unity of groups and classes and the patriotic enthusiasm of the war years he saw an opportunity, which would never be repeated, of achieving what he called "a revolution by consent." If this opportunity were missed because the Labour leaders were unwilling to threaten to resign from the coalition government, the postwar world would be neither any better nor more hopeful than the world of the 1920s and would again move toward the choice that had confronted Europe in the 1930s—reaction or revolution, fascism or communism. Laski was criticized by many people, including some of his friends in England and America, for his wartime attacks on Churchill and for his criticisms of the inadequacies and weaknesses of Attlee and other Labour party leaders.

Although the electoral victory of Labour in 1945 was a great satisfaction to Laski, the triumph was marred for him by the growing tensions on the international scene, particularly between the United States and the Soviet Union, and by his failure to win a libel action that he had instituted during the 1945 campaign, when several newspapers reported that he had made a speech in which he advocated violent revolution in Great Britain. He wrote a long book on American society and politics, *The American Democracy* (1948),

which struck many observers, including some liberals, as a curiously doctrinaire and outdated portrait of the American scene. Early in 1949, Laski made his final visit to the United States; in the course of a five-week tour of the country he delivered, under the auspices of the Sidney Hillman Foundation, the series of lectures later published as *Trade Unions in the New Society* (1949). In these lectures he urged the American trade unions to move forward to the creation of a strong labor party in order to safeguard and develop the American democratic tradition.

Although he had resigned in 1949 from the national executive of the Labour party and was worn out and ill, Laski campaigned strenuously in the 1950 general election. He died suddenly, only a few weeks after the election, on March 24, 1950.

The influence that Laski exerted by his teaching and writing was probably greatest in the 1930s; during the years of depression and the growing menace of fascism and international war, he was an impassioned advocate of socialism who combined social and economic radicalism with a deep attachment to many traditional British and American institutions and values. In this period his influence among students in both Britain and the United States was particularly great. After World War II and especially since his death, his reputation as a political theorist and analyst has been higher among students and intellectuals in Asian and African countries than among similar groups in the West.

LATENT STRUCTURE

A scientist is often interested in quantities that are not directly observable but can be investigated only via observable quantities that are probabilistically connected with those of real interest. Latent structure models relate to one such situation in which the observable or manifest quantities are multivariate multinomial observations, for example, answers by a subject or respondent to dichotomous or trichotomous questions. Models relating polytomous observable variables to unobservable or latent variables go back rather far; some early references are Cournot (1838), Weinberg (1902), Benini (1928), and deMeo (1934). These models typically express the multivariate distribution of the observable variables as a mixture of multivariate distributions, where the distribution of the latent variable is the mixing distribution [see DISTRIBUTIONS, STATISTICAL, article on MIXTURES OF DISTRIBUTIONS].

Lazarsfeld (1950) first introduced the term *latent structure model* for those models in which the variables distributed according to any of the

component multivariate distributions of the mixture are assumed to be stochastically independent. (Thus a latent structure model of a subject's answers to 50 dichotomous questions—the latent class model of this article—assumes that subjects fall into relatively few classes, called latent classes, with the variable that relates the subject to his class being the latent variable. The distribution of this latent variable, that is, the distribution of the subjects among latent classes, is the mixing distribution. Within each class it is assumed that the responses to the 50 dichotomous questions are stochastically independent.) A basic reference for the general form of latent structure models is Anderson (1959).

The present article—restricted to the case of dichotomous questions—emphasizes the problems of identifiability and efficient statistical estimation of the parameters of latent structure models, points out difficulties with methods that have been proposed, and summarizes doubts currently held about the possibility of good estimation.

The simplest of the latent structure models and almost the only one in which the problem of parameter estimation has been carefully addressed is the *latent class model*. In this model, each observation in the sample is a vector \mathbf{x} with p two-valued items or coordinates, conveniently coded by writing each either as 0 or as 1. The latent class model postulates that there is a small number m of classes, called *latent classes*, into which potential observations on the population can be classified such that within each class the p coordinates of the vector \mathbf{x} are statistically independent. This is not to say that all identical observations in the sample are automatically considered as coming from the same class. Rather, associated with each class is a probability distribution on the 2^p possible vectors \mathbf{x} , such that the p coordinates of \mathbf{x} are (conditionally) independent. An observation vector \mathbf{x} thus has a probability distribution that is a mixture of the probability distributions of \mathbf{x} associated with each of the latent classes.

An example of the above model comes from the study (Lazarsfeld 1950) of the degree of ethnocentrism of American soldiers during World War II. Because it is not known how to measure ethnocentrism directly, a sample of soldiers was asked the following three questions: Do you believe that our European allies are much superior to us in strategy and fighting morale? Do you believe that the majority of all equipment used by all the allies comes from American lend-lease shipment? Do you believe that neither we nor our allies could win the war if we didn't have each other's help?

Here $p = 3$ and \mathbf{x} is the vector of responses to the three questions, with Yes coded as 1 and No coded as 0. A suitable latent class model would postulate that there are two latent classes (so that $m = 2$), such that within each class the answers to the three questions are stochastically independent. Postulating the existence of any more than two latent classes would, as will be seen later, lead to difficulties, since the parameters of such a latent class model could not be consistently estimated. The two latent classes would probably be composed of ethnocentric and nonethnocentric soldiers, respectively. However, this need not be the case, and in fact it may happen that the two latent classes will have no reasonable interpretation, let alone the hoped-for interpretation. This phenomenon of possible noninterpretability is characteristic not only of the latent class model but also of the factor analysis and other mixture-of-distributions models.

The latent class model. Let σ denote a subset (unordered) of the integers $(1, 2, \dots, p)$, possibly the null subset ϕ . (Other subsets will, for concreteness, be denoted by writing their members in customary numerical order.) Let π_σ denote the probability that for a randomly chosen individual each coordinate of \mathbf{x} with index a member of σ is a 1, and define $\pi_\phi = 1$. For example, $\pi_{2,7,10}$ is the probability that the second, seventh, and nineteenth coordinates of \mathbf{x} are all 1, forgetting about—or marginally with respect to—the values of the other coordinates of \mathbf{x} .

Since the order of coordinates is immaterial for such a probability, one is justified in dealing with the 2^p unordered σ 's, but a specific order in naming the subset is helpful for exposition. The π_σ 's are notationally a more convenient set of parameters than what might be considered the 2^p natural parameters of the multinomial distribution of \mathbf{x} .

A concise description of the natural parameters of the distribution of \mathbf{x} is the following. Let $\bar{\sigma}$ denote that subset of the integers $(1, 2, \dots, p)$ which is the complement of σ . Let $\pi_{\sigma, \bar{\sigma}}$ denote the probability that for a randomly chosen individual each coordinate of \mathbf{x} with index of a member of σ is a 1 and each coordinate of \mathbf{x} with index a member of $\bar{\sigma}$ is a 0. The 2^p $\pi_{\sigma, \bar{\sigma}}$'s are the natural parameters of the multinomial distribution of \mathbf{x} , since they are the probabilities of each of the 2^p possible observation values. For example, in the ethnocentrism case, $\pi_{1,2,3}$ would be the probability that the first two questions are answered Yes, while the third question is answered No. The π_σ 's and $\pi_{\sigma, \bar{\sigma}}$'s are related by a nonsingular linear transformation.

Let ν_α be the probability that the observation vector \mathbf{x} is a member of the α th latent class, where

$\alpha = 1, 2, \dots, m$ and $\sum \nu_\alpha = 1$. Let $\lambda_{\alpha\sigma}$ be the probability that if \mathbf{x} is a vector chosen at random from the α th class, then each coordinate of \mathbf{x} with index a member of σ is a 1. Clearly $\pi_\sigma = \sum_\alpha \nu_\alpha \lambda_{\alpha\sigma}$.

Let σ_i denote the i th member of σ , with the members of σ arranged in some order, say numerical. The fundamental independence assumption of the latent class model then says that for each α

$$\lambda_{\alpha\sigma} = \prod_{i \in \sigma} \lambda_{\alpha\sigma_i}$$

for all σ . That is, the probability (conditional on \mathbf{x} being in the α th latent class) of any given set of coordinates of \mathbf{x} being all 1's is the product of the probabilities of each of these coordinates being a 1. Then

$$\pi_\sigma = \sum_{\alpha=1}^m \nu_\alpha \prod_{i \in \sigma} \lambda_{\alpha\sigma_i}$$

for all σ . These equations are called the *accounting equations* of the latent class model. Thus the $m(p+1)$ parameters of the model are the *latent parameters* $\lambda_{\alpha i}$ and the ν_α , $\alpha = 1, \dots, m$, $i = 1, \dots, p$. These completely determine the 2^p *manifest parameters*, the π_σ , via the accounting equations.

Parameter estimation. Suppose that the number of latent classes, m , is known to the investigator. (This assumption is made because it underlies all the theoretical work on the estimation of parameters of the latent class model. In practice m is unknown, but a pragmatic approach is to assume a particular small value of m , proceed with the estimation, see how well the estimated model fits the manifest data, and alter m and begin again if the fit is poor.) Then a central statistical problem is that of estimating the parameters of the model, the ν 's and λ 's, from a random sample of n vectors \mathbf{x} . (The typical sample in survey work is a stratified rather than a simple random sample. However, the problem of estimating latent parameters from such samples is much more complicated, and as yet has hardly been touched.)

Let n_σ be the number of vectors in the sample with 1's in each component whose index is a member of σ , and let $p_\sigma = n_\sigma/n$. If the model were simply a multinomial model with parameters the π_σ 's, then the p_σ 's would be maximum likelihood estimators of the π_σ 's. If for each set of 2^p π_σ 's there is a unique set of latent parameters, ν_α 's and $\lambda_{\alpha i}$'s, $\alpha = 1, \dots, m$, $i = 1, \dots, p$, then the ν 's and λ 's are functions of the π_σ 's, and evaluating these functions at the p_σ 's as arguments will yield estimators (actually consistent estimators) of the latent parameters. But the "if" in the last sentence is most critical; it is the identifiability condition, common

to all models relating distributions of observable random variables to distributions of unobservable random variables. Consequently, most of the work on parameter estimation in latent class analysis is really a by-product of work on finding constructive procedures, that is, procedures that explicitly derive the unique latent parameters as function of the π 's, for proving the identifiability of a latent class model associated with a given m and p . With such a constructive procedure available, one can replace the π 's by their estimates, the p 's, and use the procedure to determine estimates of the ν 's and λ 's. The following description of estimation procedures based on constructive proofs of identifiability will thus really be a description of the constructive procedure for determining the ν 's and λ 's from a subset of the π 's.

Green's method of estimation. The earliest constructive procedure was given by Green (1951). Let \mathbf{D} , be the $m \times m$ diagonal matrix with $\lambda_{\alpha i}$, $\alpha = 1, \dots, m$, on the diagonal, and let \mathbf{L} be the $(p+1) \times m$ matrix with first row a vector of 1's and j th row ($j = 2, \dots, p+1$) the vector of $(\lambda_{1,j-1}, \dots, \lambda_{m,j-1})$. Let \mathbf{N} be the $m \times m$ diagonal matrix with ν_α , $\alpha = 1, \dots, m$, on the diagonal. For σ a subset of $(1, 2, \dots, p)$, define $\mathbf{D}_\sigma = \prod_{i \in \sigma} \mathbf{D}_{\sigma_i}$. Form the matrix $\Pi_\sigma = \mathbf{LND}_\sigma \mathbf{L}'$, where the prime denotes the matrix transpose. The (i,j) th element of this matrix is

$$\sum_{\alpha=1}^m \nu_\alpha \lambda_{\alpha i} \lambda_{\alpha j} \prod_{i \in \sigma} \lambda_{\alpha \sigma_i}.$$

If $i \neq j$ and $i, j \notin \sigma$ then the (i,j) th element of this matrix is the manifest parameter $\pi_{ij\sigma}$. Otherwise the (i,j) th element of this matrix can formally be defined as a quantity called $\pi_{ij\sigma}$, where the subscript of π may have repeated elements. Since π 's with repeated subscripts are not manifest parameters and have no empirical counterpart but are merely formal constructs based on the latent parameters, they are not estimable directly from the n_σ 's. However, Green provided some rules for guessing at values of these π 's (one rule is given below) so that the matrix Π_σ can be partly estimated and partly guessed at, given data.

Let $\Pi_0 = \mathbf{LNL}'$, \mathbf{N} be the $m \times m$ diagonal matrix with $\sqrt{\nu_\alpha}$, $\alpha = 1, \dots, m$, on the diagonal, $\mathbf{D} = \sum_{k=1}^p \mathbf{D}_k$, and $\mathbf{A} = \mathbf{LN}$. Then $\Pi = \sum_k \Pi_k = \mathbf{ADA}'$. Under the assumptions that $m \leq p+1$, rank $\mathbf{A} = m$, and all the diagonal elements of \mathbf{D} are different and nonzero, the following procedure determines the matrices \mathbf{L} and \mathbf{N} of latent parameters.

Factor Π_0 as $\Pi_0 = \mathbf{BB}'$ and $\Pi = \mathbf{CC}'$. (The matrices \mathbf{B} and \mathbf{C} are not unique, but any factorization will do.) Let $\mathbf{T} = (\mathbf{BB}')^{-1} \mathbf{B}' \mathbf{C}$. A complete

principal component analysis of TT' will yield an orthogonal matrix Q , and it can be shown that $A = BQ$. Since the first row of L is a vector of 1's, the first row of A is an estimate of the vector $(\sqrt{\nu_1}, \dots, \sqrt{\nu_m})$, so that N is easily determined. The matrix L is then just AN^{-1} .

The major shortcoming of this procedure is the problem of how to guess at values of the π 's bearing repeated subscripts. No one has yet devised a rule which, when applied to a set of p 's, will yield consistent estimators of L and N . For example, Green suggests using $p_{ii} = p_i^2 + \max_{j \neq i} (p_{ij} - p_i p_j)$ as a guess at π_{ii} . Yet in the case $m = 2$, $p = 3$ with latent parameters $\nu_1 = \nu_2 = .5$, $\lambda_{11} = .9$, $\lambda_{12} = .2$, $\lambda_{21} = .8$, $\lambda_{22} = .7$, $\lambda_{32} = .9$, $\lambda_{33} = .4$, if $i = 2$, $\max_{j \neq 2} (p_{2j} - p_2 p_j)$ is a consistent estimator of $-.07$, so that p_{22} is a consistent estimator of something smaller than π_{22}^2 . But $\pi_{11} \geq \pi_{22}$, so that p_{22} is not a consistent estimator of π_{22} .

Determinantal method of estimation. A matrixial procedure that does not have the above shortcoming, since it involves only estimable π 's, was first suggested by Lazarsfeld and Dudman (see Lazarsfeld 1951) and independently by Koopmans (1951), developed by Anderson (1954), and extended by Gibson (1955; 1962) and Madansky (1960). For ease of exposition, the procedure will be described only for the cases treated by Anderson.

Assume that $p \geq 2m + 1$. In that case, $2m + 1$ different items can be selected from the p items (say, the first $2m + 1$) and the following matrices of π 's involving only these items formed. Let

$$\Pi^* = \begin{bmatrix} 1 & \pi_1 & \cdots & \pi_m \\ \pi_{m+1} & \pi_{1,m+1} & \cdots & \pi_{m,m+1} \\ \vdots & \vdots & \ddots & \vdots \\ \pi_{2m} & \pi_{1,2m} & \cdots & \pi_{m,2m} \end{bmatrix}$$

and let $\tilde{\Pi}$ be the matrix Π^* with the 1 replaced by π_{2m+1} and all the π 's having the additional subscript $2m + 1$. Let Λ_1 be an $(m + 1) \times (m + 1)$ matrix with the first row a vector of 1's and the j th row ($j = 2, \dots, m + 1$) the vector $(\lambda_{1,j-1}, \dots, \lambda_{m,j-1})$, and let Λ_2 be an $(m + 1) \times (m + 1)$ matrix with first row a vector of 1's and the j th row ($j = 2, \dots, m + 1$) the vector $(\lambda_{1,m+j-1}, \dots, \lambda_{m,m+j-1})$. Let N and D_{2m+1} be defined as above. Then $\Pi^* = \Lambda_1 N \Lambda_2'$ and $\tilde{\Pi} = \Lambda_1 N D_{2m+1} \Lambda_2'$. Thus, if the diagonal elements of D_{2m+1} are distinct and if Λ_1 , N , and Λ_2 are of full rank, then the diagonal elements of D_{2m+1} are the roots θ of the determinantal equation $|\tilde{\Pi} - \theta \Pi^*| = 0$.

Table 1

Parameter	Value	Asymptotic variance
ν_1	3/4	1115.42 n
λ_{11}	1/2	39.00 n
λ_{12}	1/3	60.89 n
λ_{13}	1/3	4.96 n
λ_{21}	1/4	303.00 n
λ_{22}	2/3	611.53 n
λ_{23}	1/4	31.00 n

If Z is the matrix of characteristic vectors corresponding to the roots $\theta_1, \dots, \theta_m$, then the columns of $\Pi'Z$ are proportional to the columns of Λ_1 , with the constant of proportionality determined by the condition that the first row of Λ_1 is a vector of 1's. A similar argument using the transposes of $\tilde{\Pi}$ and Π' yields Λ_2 , and N is determined by $N = \Lambda_1' \Pi' \Lambda_2'^{-1}$.

A difficulty with this procedure is that it depends critically on which $2m + 1$ items are chosen from the p items, on which of these $2m + 1$ is chosen to define Π' , and on the allocation of the $2m$ items to the rows and columns defining Π' . That is, it depends critically on the ordering of the items. There are no general rules available for an ordering of the items that will yield relatively efficient estimators of the latent parameters.

The most important shortcoming of this procedure and of its extensions (which involve more of the π 's) is that there is no guarantee that when the procedure is used with a set of p 's it will produce permissible estimates of the latent parameters, that is, estimates that are real numbers between 0 and 1. In four sampling experiments with $n = 1,000$, $m = 3$, and $p = 8$, Anderson and Carleton (1957) found that of 2,240 determinantal equations only 33.7 per cent had all roots between 0 and 1. Madansky (1959) computed the asymptotic variance of the determinantal estimates for the case $m = 2$, $p = 3$, a case in which these estimators, if permissible, are the maximum likelihood estimators of the latent parameters, and found the results presented in Table 1, where n is the sample size. Thus, sample sizes must be greater than 1,116 for the variance of the estimators of all the parameters to be less than 1.

Table 2

$\pi_{1,23} \phi$	= 10 192
$\pi_{23,1}$	= 14 192
$\pi_{13,2}$	= 17 192
$\pi_{12,3}$	= 22 192
$\pi_{3,1,2}$	= 19 192
$\pi_{2,1,3}$	= 34 192
$\pi_{1,2,3}$	= 35 192
$\pi_{\phi,1,2,3}$	= 41 192

Table 3

Response pattern	Number observed
123; ϕ	2
23;1	3
13;2	4
12;3	4
3;12	4
2;13	7
1;23	7
ϕ ;123	9

Rounding error also affects the estimates greatly. The parameters of the multinomial distribution for the above model are given in Table 2.

For a sample of size 40, if one had actually observed the expected number of respondents for each of the response patterns (rounded to the nearest integer), then the sample would have the composition shown in Table 3. Table 4 shows the p_σ 's based on these data (π_σ being given for comparison). The determinantal estimates of the latent parameters are given in the third column of Table 5. (The fourth column will be discussed below.)

Partitioning method of estimation. A third estimation procedure (Madansky 1959) looks at the problem in a different light. Since the latent classes are defined as those classes within which the p components of the vector \mathbf{x} are statistically independent, one might (at least conceptually) look at all possible assignments of the n observations into m classes and find that assignment for which the usual χ^2 test statistic for independence is smallest. The estimates of the latent parameters would then just be the appropriate proportions based on this best assignment. They would always be permissible. Although for finite samples they would not be identical with minimum χ^2 estimates, they would have the same asymptotic properties and thus be asymptotically equivalent to maximum likelihood estimates.

Madansky (1959) introduced another measure of independence, simpler to compute than χ^2 , and found that the asymptotic efficiency of the estimators of the latent parameters from this procedure, in the example described above, is about .91. The obvious shortcoming of this idea is that it is too time consuming to carry out all the possible assign-

Table 4

σ	p_σ	π_σ
1	.425	.4375
2	.400	.4167
3	.325	.3125
12	.150	.1667
13	.150	.1406
23	.125	.1250
123	.050	.0521

ments, even for moderate samples on an electronic computer. In the example described above, for a sample of size 40 it took four hours of computation on the IBM 704 to enumerate and assess all the assignments into two classes. The resulting estimates are shown in the fourth column of Table 5.

Table 5 — Parameter estimates for two methods*

Parameter	Value	Determinantal estimate	Partitioning estimate
ν_1	.75	.23	.58
λ_{11}	.50	.82	.00
λ_{12}	.33	.23	.43
λ_{13}	.33	.42	.30
λ_{21}	.25	.30	1.00
λ_{22}	.67	.45	.35
λ_{23}	.25	.29	.35

* $n = 40$.

Scoring methods. Current activity on estimation procedures for the latent class model (Henry 1964) is directed toward writing computer routines using the scoring procedure described by McHugh (1956) to obtain best asymptotically normal estimates of the latent parameters. The scoring procedure will yield estimators with the same large asymptotic variances as those indicated by the above example of the maximum likelihood estimators' asymptotic variances. Also, the scoring procedure has the same permissibility problem associated with it as did the determinantal approach described above. However, the problem can be alleviated for this procedure by using a set of consistent permissible estimators for initial values in the scoring procedure.

LATIN AMERICAN POLITICAL MOVEMENTS

The dominant characteristic of twentieth-century Latin America is the pressure for fundamental change—social, economic, and political change. In several nations, governments committed to such change have come to power. Even in many of the nations where conservative oligarchies maintain their hold, the pressures for change are such that few governments have believed it wise to ignore them completely. Dynamic forces are at work: population growth, urbanization, industrial development, growth of labor unions, the appearance and

increasing influence of certain political parties, and an increasing demand on the part of the underprivileged and depressed mass of people for a better material life ("the revolution in rising expectations"). These forces have promoted, and to some degree have been promoted by, the emergence of several radical or reformist political movements during this century. The major ones are the Mexican revolution, the Uruguayan reforms (Batllism), the Apristas, Peronism, the Vargas movement, the Christian Democrats, and Castroism.

General characteristics and influences

Considerable similarity exists among these movements. They advocate development and various economic reforms, a strong government and a larger role for government, especially in the economic and social areas, and social reforms (e.g., increased literacy, expanded educational opportunities, social welfare programs). They appeal to and in varying degrees involve the masses. They urge either a breaking down or a modifying of traditional class lines and concomitantly urge broader mass participation in national life. In their economics most movements embrace some form of socialism. They are nationalistic and, either as an aspect of nationalism or as a separate ingredient, they inveigh against economic and political imperialism. Their anti-imperialism may be simply a negative, anti-United States sentiment, or it may be an aspect of a more positive phenomenon: a prohemispheric or pro-Latin American sentiment.

Numerous differences also exist among the movements. Some have a well-developed theoretical or philosophical base (especially the Apristas and the Christian Democrats); others are primarily pragmatic. They differ in the stress put on certain goals. Perhaps the major differences concern means of achieving desired changes and the kind of society that would be created. These differences are the effect of several factors: the level of social, economic, and political development; the political situation; and the variety of attitudes, inclinations, and estimations of the individuals who provide or have provided both intellectual and practical leadership for the movements.

The stress that twentieth-century movements put on change places them in sharp contrast with the political thought that previously dominated Latin America. That thought, primarily European in origin, was the monopoly of the small elite that had enjoyed political and economic power and high social status since independence. Reflecting the interests of the elite, the earlier thought either defended the *status quo* or urged relatively minor

change, usually of a political nature (e.g., changes in electoral laws). In those instances where the principles advocated cannot be termed "minor" (e.g., matters in the area of church-state relations), they did not call for fundamental changes, nor were the changes called for intended to affect the masses. Where concerned with economic matters, the earlier thought proposed relatively moderate changes. Comtean positivism, the single most influential line of political thought in late nineteenth-century Latin America, emphasized a free secular society and the idea that the growth of knowledge gradually promoted political freedom and economic improvement. In short, the earlier political thought—still dominant in some of the nations—did not advocate a restructuring or reorganization of society; the newer political thought does.

This article will focus first on general factors influencing the new political thought, and then on each of the twentieth-century political movements and the methods it endorsed or employed to promote change.

The factors that have molded or influenced the movements may be classified as primarily material or primarily intellectual. These, in turn, may be classified as indigenous or nonindigenous, positive or negative influences.

Material influences. The most obvious and the single most important material influence is negative and indigenous: the reaction against prevailing economic conditions. Indeed, this is usually the main goal of all the movements, for other goals are seen to be directly related to it. The movements insist that conditions must be changed and advocate a massive, multipronged program of economic development. To some degree the desire for economic development may be attributed to the positive, nonindigenous influence of the world's mature economies, since economically less-developed nations desire to have the same level of economic well-being and diversity of economic activity. (This desire does not mean, however, that Latin America accepts the economic principles of the mature economies.)

A second influence, also negative and indigenous, is the reaction against prevailing social conditions. A large part, in some cases a majority, of the population is cut off from national life, living in a depressed condition without opportunity to achieve a better status. The movements pledge to improve the lot of this segment of the population and appeal to it for support.

Prevailing political conditions are a third negative, indigenous influence. Democratic forms (con-

stitutions which are often modeled after that of the United States and provide for separation of powers, bills of rights, political parties, elections, and a variety of special devices to ensure democratic government) have long existed, but in many of the Latin American nations political practice has been quite undemocratic. Further, government, whether military or civilian, has been *by* and *for* the small elite, usually ignoring the needs of the masses. All of the movements advocate change in the political process. They may not agree on the kind of political system or how it should function, but they do agree that government by them and based on their principles will not be government devoted to promoting and protecting the interests of the elite. It will be government for (although not necessarily by) the masses.

Another negative influence, both indigenous and nonindigenous, on all of the movements (except perhaps Batllism) is the resentment against the economic and political influence the United States has long had and still has in Latin America. Limitation, if not elimination, of U.S. influence is a goal of the twentieth-century movements. Proposed means of accomplishing this end include controls on foreign capital, nationalization of some or all foreign investment, closer cooperation among Latin American nations, and creation of a new inter-American organization. The extent and intensity of efforts to reduce U.S. influence vary, of course, from movement to movement and from time to time.

Intellectual influences. For the most part the programs put forward by the movements are not borrowed ones. Rather, they are a response to local conditions. Nevertheless, various "outside" ideas and events have influenced all of the movements. European socialism, including Marxism, has had a tremendous impact on most of the movements. The same is true of French, British, and United States liberal thought. The notion of Latin American unification can be traced back to the liberator Simón Bolívar, and the ideal has been embraced by a host of persons in succeeding years. Similarly, the *Aprista* emphasis on the development of an Indian or Indo-American culture has some roots in Latin American thought.

The economic and social reforms of President Franklin D. Roosevelt (the New Deal) had an impact on several of the movements. The same can be said of the British Labour party and the development program "Operation Bootstrap" carried out by Muñoz Marín in Puerto Rico.

Since the end of World War II, the "new economics" of Raúl Prebisch and the United Nations

Economic Commission for Latin America has been the major influence on Latin American economic thought.

The major movements

The Mexican revolution and the Uruguayan reforms may be added to the list of general influences, since these movements preceded the others and have served as examples, if not as models. They will therefore be discussed first.

The Mexican revolution. The Mexican revolution, the foremost political movement of twentieth-century Latin America, began in 1910 under the leadership of Francisco I. Madero as a revolt against the dictatorship of President Porfirio Díaz. Its original objectives were entirely political, as epitomized by Madero's slogan, "Effective Suffrage! No Re-election!" As the revolt spread and its support increased, it became a full-blown social revolution. Economic and social objectives—land reform, economic development, restrictions on the church and foreign capital, integration of the Indians, destruction of the existing class structure and class barriers—were added to the political objectives. Civil war raged until 1916. Thereafter order was progressively restored, and implementation of the revolutionary program began on a nation-wide scale.

The revolutionary program. The revolution was pragmatic and evolutionary, not ideological. No master plan existed concerning the implementation of objectives. The revolution consisted of a series of acts, and often these acts were experiments. As Robert Scott says, "Mexico had no Marx to supply a theoretical, rational, and systematic model for its revolution. And somehow history failed to produce any single dominant personality who could perform this service. . . . Probably the movement was too big, too diverse, and too spontaneous to be identified with any one program or person" ([1959] 1964, p. 98). To answer the question "What was the Mexican revolution?" one must look at what was done.

The best place to begin is the constitution of 1917. That document expresses the objectives of the revolution and gives considerable insight into its philosophy. It is a hybrid, because ". . . it retained the ideals of liberalism while placing the interests of society and of the state above those of the individual" (Ross 1963, p. 89). Three articles are especially worthy of note. Article 3 assigns to the national government responsibility for providing free, public elementary education. The article reflects the importance attached to education by the revolutionary leaders and the anticlerical bent

of the revolution. Article 27 deals with landownership and the rights of foreign capital, limits the size of agricultural holdings, and asserts the nation's control over the subsoil. Property is held to have a "social function," with the rights of private property subordinated to "social welfare." The article expresses several tenets of the revolution: hostility to the *hacienda*, commitment to agrarian reform, determination to overhaul the prerevolutionary class structure based on landownership, anticlericalism (for the church was a large landowner), opposition to foreigners, and nationalism. Article 123 assigns to the state the task of promoting, protecting, and regulating the labor movement and spells out the economic and social rights of labor. "The basic principle of Article 123 was that labor was a status, a way of life, for which the minimum essentials were now constitutionally guaranteed, rather than an economic commodity, subject to the market vagaries of supply and demand" (Cline 1953, p. 169). The article reflects the role—both the right and responsibility—assigned to the state in promoting social welfare, the effort to enhance the position of the working class, and concern with industrialization and the urban sector of the economy.

An extensive land reform program was begun in the early 1920s. Under this plan, land, either government-owned or taken from persons owning more than 5,000 hectares, was distributed to landless peasants. While some land was given outright to the peasants, most of it was given to village communities, *ejidos*. The *ejido* is not a collective farm; rather, it is a form of landholding with historical antecedents both in Spain and in pre-Hispanic Mexico. *Ejido* land is divided among the families of the community and is worked by them as individual units. Although the *ejidatario* cannot alienate his land, he can pass it on to his heir. By the mid-1960s, 40 to 50 per cent of the cropland was in *ejidos*, and about 30 per cent was in small and medium-size private holdings (Needler 1964, pp. 21–22).

During the early years of the revolution relatively little was done in the economic area apart from land reform, despite the declared objective of economic development. Admittedly some actions were taken that had economic effects (for example, nationalization of agricultural lands, railroads, and petroleum), but they were socially and politically, not economically, motivated (Cline [1962] 1963, p. 231). And the few economic programs that were attempted were unsuccessful.

The desire for economic independence, plus the adverse effects of the great depression and World

War II, dramatized the need for action and led to the inauguration of a development program. One part of this program was to increase the tempo of land reform. Another part, the key, was industrialization, and through various inducements a high rate of industrial development has been achieved. Industrialization is, in large part, the result of a shift in Mexican attitudes toward foreign capital; it is no longer rejected, but is welcomed. This shift in attitude is only one manifestation of a more general phenomenon: moderation of the revolution. (Such moderation is typical of radical movements once they have achieved power and consolidated their position.) However, the government is at least partially enforcing "Mexicanization" laws, which require that Mexicans must own 51 per cent of all business enterprises.

The economic and social programs accomplished fundamental change. The class structure was revamped and the prerevolutionary landowning elite was replaced by a new upper class whose wealth is in industry, commerce, and finance. A large, predominantly urban and industrial middle class has developed. The urban and rural masses have benefited, although the benefits have been limited. However, there has been much upward mobility of individuals *between* classes, and it is primarily through such individual mobility that substantial improvements in the real standard of living of the urban and rural proletariats can result (Needler 1964, p. 31).

The political objectives of the revolution have been implemented. Governmental stability has been achieved. "Effective Suffrage! No Re-election!" has been effected. A fairly high level of democracy prevails. Government is sensitive to citizen wants. Opposition groups are free to organize and operate. Civil liberties exist.

Mexico's foreign policy is based on the principles and experiences of the revolution: national sovereignty, juridical equality of nations, self-determination, and nonintervention. The Estrada doctrine, a Mexican contribution to international legal ideas, asserts that granting or withholding of diplomatic recognition at a government's discretion constitutes interference in the affairs of another state. Recognition should, therefore, be automatic.

Theory and philosophy. Although not an ideological movement, the revolution was not devoid of political thought. A list of writers would include (but not be limited to) Andres Molina Enríquez, Jesús Silva Herzog, Graciano Sánchez, Vincente Lombardo Toledano, Manuel Gamio, Gilberto Loyo, Fernando Gonzales Roa, Daniel Cosío Villegas, and Gómez Morin.

Uruguayan reform (Batllism). A much different but only slightly less important movement (Batllism) remade Uruguay during the first quarter of the twentieth century under the leadership of José Batlle y Ordóñez. Like the Mexican revolution, Batllism was concerned with social, economic, and political problems. Also like the Mexican revolution, it was pragmatic, not ideological. Unlike the Mexican revolution it was a peaceful movement and did not touch the whole population; its impact was primarily urban.

The program. The actions taken under Batllism earned for Uruguay the reputation of being one of the world's most advanced laboratories for political, social, and economic experimentation (Fitzgibbon 1954, pp. 96-97).

The social and economic aspects of Batllism—which constituted a high degree of state socialism—can be described by citing what was done during Batlle's two presidential terms, 1903-1907 and 1911-1915. His proposal for an eight-hour working day and a weekly rest period was enacted, as were laws to protect the worker's life and health and to encourage labor union activity. During Batlle's presidency elementary education was made obligatory and education at all levels was made free. New schools were constructed; a women's university was established. Foreign professors and technicians were brought to Uruguay, and scholarships were given for study abroad.

Various social service measures were also enacted. Laws were passed giving protection to women, children, the sick, and the elderly. Women were emancipated. Divorce was legalized. Tax was abolished on the earnings of the lowest-paid public officials and on the smallest pensions.

Furthermore, steps were taken to stimulate industry. Immigration was encouraged. A state insurance monopoly was created. The Bank of the Republic was nationalized. Several government-owned and government-operated industries were established to provide certain basic products at a low price and to reduce dependence on imports. Railroads, power facilities, meat-packing plants, and some other businesses were nationalized.

Although Batllism focused attention on urban, industrial problems, some attention was also given to the agricultural sector. Stock raising and agriculture received governmental assistance. Rural credit facilities were established. Agricultural research was promoted. Import duties on agricultural tools and machinery were removed. To some degree, the agricultural programs may have been a means of "buying" rural toleration, for Batlle was detested and opposed by the large landowners.

From the perspective of the second half of the twentieth century, Batlle's reforms may seem extremely mild, but for the first quarter of the twentieth century they were radical.

The political reforms were equally radical. Batlle saw a Uruguay plagued with political problems, e.g., dictatorship, instability, and civil strife. He blamed these problems on the domination and abuses of past presidents. To overcome the problems, Batlle proposed the abolition of the presidency and the establishment of a nine-member executive council (modeled on the Swiss collegial executive) with three of the seats assigned to the minority party. Further, he proposed that congressional elections be conducted on a proportional representation system. The proposal met with hostility, especially from his own party, and was not adopted until 1919 (after Batlle was out of office)—and then in limited form. The bi-partisan collegial executive was abandoned in 1933 but re-established, and in the form Batlle envisioned, in 1951. Batlle's political reforms are largely responsible for the high level of democracy that prevails in Uruguay.

Theory and philosophy. Very little theoretical writing is associated with Batllism. Batlle's ideas are expressed in his articles in *El Día*, his newspaper. But the articles "do not form a very systematic whole, since he did not generally concern himself with the philosophical base of ideas" (Davis 1958, p. 103).

The "Apristas." Between the two world wars Peru produced a distinctive ideological party, the Alianza Popular Revolucionaria Americana (APRA), whose ideology was popularly known as *aprimo* and whose members were called *Apristas*. The party dates back to 1914, but it was not formally organized until 1931. Led by Victor Raúl Haya de la Torre, the *Apristas* have had an almost hemisphere-wide influence, and *Aprista*-type parties have been founded in these areas and countries: in Cuba, Partido Revolucionario Cubano (Auténtico); in Venezuela, Acción Democrática; in Costa Rica, Liberación Nacional; in Paraguay, Partido Febrerista; in Haiti, Mouvement Ouvrier et Paysan; and in Puerto Rico, the Popular Democratic Party. However, there was little contact between the *Aprista* parties during their formative years.

Aprismo was begun by a group of students at Lima's University of San Marcos who led a successful effort to reform the school. Their next step was to establish night schools for adults, in order to raise the economic and social level of the illiterate (Kantor 1953). The government sup-

pressed the schools and exiled the student organizers, who then decided that political action was necessary and developed the *Aprista* ideology.

The ideology. *Aprismo* is a blend of ideas and ideals about the uniqueness of Latin America and democratic socialism. The aim is to create a "new" Peru and a "new" Latin America. The basic thesis is that Latin America is unique; it is different from the United States and Europe, and must cease imitating their institutions and create its own Indo-American culture. (The thesis is related to Haya's historical space-time theory, which holds that there is no single theory or explanation of history valid for all societies.) Its over-all plan consists of two parts: a "maximum program" for all Latin America and a "minimum program" for Peru only. The principles of the maximum program are integration or assimilation of the Indian population, opposition to imperialism, unification of the Latin American nations, a planned economy including nationalization of land and business, and democratic government.

Aprista thinkers stress the need to integrate the Indian into society. To the *Apristas*, Latin America will not realize its economic or political potential until the Indian has been integrated. Two conflicting cultures are said to exist in Latin America, one European, the other indigenous, or Indian. The result is instability. A stable society will be possible in Latin America only when the two clashing cultures are merged. The *Apristas* believe that their program would amalgamate the Indian and Europeanized sections and produce a *new*, integrated Indo-American culture containing elements from both (Kantor 1953). Integration would not be easy or quick, and to achieve it several actions would be necessary: free, state-controlled education, including technical education; agrarian reform (formation of cooperative farms, government authority to regulate land purchases and sales, programs to increase productivity, and dissemination of technical information); and laws to enhance the position of labor (wage and hour laws, retirement benefits, employment services, organization of unions).

Anti-imperialism is another major tenet. Indeed, the *Apristas* believe that the most important problem facing Latin America is that created by imperialistic penetration. Imperialism, held to be economic in nature, is explained in the following terms:

Outward expansion is inevitable in a highly industrialized country based on the capitalist system of production. As the *Apristas* see the process, capitalism forces an industrially developed country to seek raw

materials in the underdeveloped areas of the world. At the same time, an industrial country must seek markets for the manufactured goods which cannot be consumed at home. (Kantor 1953, pp. 37-38)

And in an alliance with local elites, foreign capital gained control of the Latin American economies. However, the *Apristas* do not reject foreign capital; they recognize that it has made a contribution and can continue to do so. But foreign capital must be controlled to ensure that it plays a "useful role." Without eliminating their opposition to imperialism, *Aprista* leaders have over the years moderated their statements on this subject.

The *Apristas* hold that unification of Latin America is the only means of combating imperialism and strengthening Latin America. They see Latin America as a single "natural unit." Existing boundaries have no justification, being mere carry-overs from the colonial period that perpetuate economic feudalism. *Apristas* insist that unification would not be difficult. There are, they say, more similarities than differences among the hemisphere's people. Unification is necessary for defense. Further, realization of increased economic and political strength should be sufficient to overcome any hurdles that may exist. Two strong but not insurmountable forces—U.S. imperialism and the elite—work against unification. Although opposed to U.S. imperialism, the *Apristas* are not anti-United States. They desire to cooperate with the United States, seeing cooperation as a benefit to both parties. And Latin American unification is seen as a means of promoting cooperation by putting Latin America and the United States on an equal footing.

Economic development is a goal. Originally nationalization of industry and land was posited as the ideal form of economic organization. However, nationalization was a long-range goal, and the means of achieving it was spelled out. Nationalization is another area in which *Aprista* doctrine has changed; a mixed economy is now envisioned.

Haya de la Torre and other Peruvian *Aprista* leaders insist that the political process must be democratic, and they refuse to use force to obtain power. One author states that the most conspicuous weakness of the Peruvian *Apristas* is their neglect of the means of achieving power (Kantor 1953, p. 1). Asked why the *Apristas* have not used force, Haya replied "... that although the *Apristas* were not pacifists, they were convinced that the experience of history demonstrated that the use of violence in politics exposed its users to the danger of degenerating into complete dependence upon violence..." (Kantor 1953, p. 56). However, not all *Aprista*-type parties have refused to use force.

In Venezuela, Acción Democrática joined with segments of the military to overthrow a government, and when it came into power, established a democratic political process.

The Peruvian *Apristas* endeavor to make their movement more than a political party, seeing themselves as soldiers in a crusade and as seekers of educational purification which will transform Peru into a modern, democratic nation. They want to establish a high standard of living, but even more important than that, they want to see a spiritual renovation within Peru which will create a new country based on a morally changed people (*ibid.*, p. 61). In short, they seek to make *aprismo* a way of life.

Theory and philosophy. The theory and philosophy of *aprismo* is expressed in countless works and by numerous writers. Of the writers, Haya de la Torre stands out. Others who should be mentioned include Manuel Seoane, Luis Alberto Sánchez, Alfredo Saco, and Carlos Mariategui (a founder of *aprismo* who later embraced international communism).

Peronism. Argentina's Peronist movement began in 1945: the following year the movement's leader, Juan D. Perón, was elected president of Argentina; he and his program then dominated the nation until mid-1955. Although Peronism wrought change, the change was not as fundamental as in the Mexican revolution and Batllism or in the *Aprista* program. Nevertheless, Peronism had a tremendous impact on Argentina, and despite the dictatorial, corrupt nature of Perón's regime and its eventual collapse, its impact has not been eradicated—probably cannot be eradicated.

Some have labeled Peronism as fascism (Lipset 1960, pp. 173-176). Still others reject the label (Silvert 1963, pp. 361-366), and the latter individuals may have the better case. Granted Perón may have been favorably impressed by Franco's Spain and Mussolini's Italy and some of his statements had fascist or profascist overtones. But Peronism differed from European fascism in fundamental ways. Actually, Peronism was nonideological, despite the appearance of *justicialismo*—the so-called ideology of the movement. The term *justicialismo* did not appear until 1949 (Blanksten 1953), and the *justicialist* ideas were propounded after that. *Justicialismo*—the "balancing of forces" or "Third Position"—never passed beyond being whatever Perón did or said.

The program. Peronism advocated the "economic independence of Argentina," and to this end a primarily industrial development program was pursued to free the country from dependence on

agriculture, imports, and foreign capital. As part of the development program, and as part of the nationalism that characterized Peronism, the government nationalized some industries and took over foreign-owned transportation and communications facilities. In typical twentieth-century Latin American fashion, private property was held to have a "social function" and was subordinated to state regulation.

The heart of Peronism was the program of "social justice." That program was directed toward the great mass of workers (the *descamisados*), who lived in ignorance and poverty and whose minimum wants and needs were ignored by the privileged members of society (Edelmann 1965, p. 354). A large body of social and labor legislation was enacted. The social and economic rights of the masses were written into the 1949 constitution. The *descamisados* were molded into a political force and a source of support by Perón, who, in return, rewarded them with social and economic benefits, a voice in government, and a government that was sympathetic to their needs and wants. (Perón's wife, Evita, played a major role in the program of "social justice.") The benefits were achieved at a price in addition to their financial cost: a loss of freedom of action.

Perón attempted to export his movement, or at least his influence, through labor attachés in Argentine embassies in Latin America, through general publicity, and through contacts with military leaders in other Latin American nations. And although Peronist governments did not come to power elsewhere in Latin America, Perón's efforts had some political impact in other Latin American nations.

The program was, however, very limited. The land tenure system was not changed. Wealth was not redistributed. The pre-Perón social class structure was not overthrown. And a question may be raised if Peronism was anything more than a typical Latin American dictatorship. Davis, for example, says Peronism was simply "a shrewd mixture of militarism, economic planning, and a demagogic appeal to the underprivileged [cemented with] a long overdue program of labor and social legislation" (1958, p. 112). Certainly Perón "governed internally by juggling already existing power centers in a fashion typical of states in immediately prenational situations, and . . . the regime even toppled in traditional . . . Latin American style" (Silvert 1963, p. 366). The power centers referred to were the army, the church, the oligarchy, "foreign imperialists," the interior, the *porteños*, and a new one, labor.

But the importance of Peronism must not be underestimated. The workers saw a government aware of their needs that allowed them a certain degree of participation in the political process, and, perhaps equally important, even the integrated middle and upper classes were finally willing to admit the alienation of some of their fellow citizens. Most of all, Peronism convinced the workers that much could be done by government to improve their lot. As a result, Peronism—even without Perón—remains a political force in Argentina.

Theory and philosophy. Peronism, a pragmatic movement, at first borrowed from the Neo-Thomism of Nicolas Desiri, an Argentine priest and philosopher, and from the ideas of Hernán Benítez, whose writings appeared in the *Revista de la Universidad de Buenos Aires*. After 1949, Peronism sought to develop its own ideology, *justicialismo*. Three men in particular endeavored to make it a social and political philosophy: Raúl A. Mende, Julio Claudio Otero, and Luis C. A. Serras. However, it is in the speeches of Perón and his wife that one finds most of the ideas of Peronism.

The Vargas movement. The major twentieth-century political movement in Brazil was that of Getúlio Vargas, who headed the government from 1938 to 1945 and from 1950 to 1954. In many respects, the Vargas and Perón movements are of the same species. Originally Vargas relied for support on the *tenentes* (a group of young officers and civilians), but gradually he expanded his base through appeals to the discontented. Shortly before the 1938 election, Vargas promulgated a new constitution (the *estado novo* constitution) with features resembling Portuguese corporatism and Italian fascism. But the resemblance "was rather superficial; . . . the *estado novo* . . . is better understood as the product of Brazilian social and political elements" (Davis 1958, p. 109).

The program. Vargas pushed economic development. The government built highways and railroads. A development commission was established to promote industry and commerce—Vargas' principal objective. Education was promoted. Social and labor measures were enacted. Of all the decisions made by Vargas, probably none had greater political implications than his determination to bring the working groups into the political arena. Vargas retained their approval through elaborate welfare programs and by imposing restrictions and obligations on business and management. At the same time he maintained strict federal control over the labor movement as a guarantee to the business community that labor would not be permitted to get out of hand (Johnson 1958, pp. 167–168).

The movement contained a strong element of nationalism. One expression of this nationalism was the law providing that two-thirds of the workers in every enterprise had to be Brazilian. Another expression, the most dramatic, was construction of the Volta Redonda steel plant.

The importance of the movement did not end with Vargas' death in 1954. The forces activated or promoted by him retain much political influence.

Theory and philosophy. The Vargas movement evolved no political theory of its own. Vargas' speeches were pragmatic and opportunist, not theoretical. Francisco Campo's *O estado nacional*, published in 1940, was widely but wrongly viewed as the regime's fascist theory (Loewenstein 1942).

The Christian Democrats. The Latin American political movement growing most rapidly in strength and influence is Christian Democracy. The movement is not new. The first Christian Democratic party was established in 1910 (in Uruguay), and since then Christian Democratic parties have been established in all the nations except Cuba, Haiti, Honduras, and Paraguay (Edelmann 1965, p. 355). Its growing influence is, however, a recent development (Szulc 1965). In 1958, a Christian Democratic party, COPEI, became the second largest party in Venezuela. In 1964, the Christian Democratic candidate, Eduardo Frei, was elected president of Chile, and the following year the party gained control of the lower house of congress.

The movement possesses a well-developed ideology, of European origin, adapted to fit the Latin American scene. It was greatly influenced by the writing of the Catholic philosopher Jacques Maritain, a spokesman for liberal Thomism. Frei is the leading Latin American spokesman of the movement.

The ideology. Christian Democracy is based on the Christian ethic. More specifically, it is based on the tenets of Roman Catholicism, especially the encyclical *Rerum novarum*, issued by Pope Leo XIII in 1891. That encyclical, the so-called Magna Carta of labor, declared that laborers had the right to organize and the employer had an obligation to pay a fair wage.

Latin American Christian Democracy is reformist, and left of center or leftist. Its leaders are committed to achieving a social revolution through evolutionary means. Their objective is a society of social and Christian justice for all. They are committed to democracy—a political system *by* and *for* all the people. "Democracy," Frei writes, "will not be saved by those who, praising it as it now exists, petrify its abuses. Much less will it be saved by those who see only its defects and not its infinite

possibilities. . . . Our task is to realize the possibilities of democracy" (see statement in Pike 1964, p. 213). Frei argues that democracy does not in fact exist when a sizable portion of the population is not incorporated into society—a common phenomenon in Latin America. "In order to acquire and preserve the precious gifts of democracy it is necessary," Frei declares, "to incorporate this proletariat into the national existence" (*ibid.*, p. 217).

The programs of Latin American Christian Democratic parties differ from nation to nation. Some general comments may be made about the Chilean party, not because it is a "typical" Christian Democratic party but because of its political power. The Chilean Christian Democrats reject both capitalism and communism. They condemn capitalism as "merciless" and "degrading of human dignity" and brand communism as "totalitarian" and "undemocratic" (Bray 1965, p. 24).

They advocate a middle way, a "communitarian society," characterized by labor's involvement in management and ownership, and government action to prevent "economic concentration" (Sigmund 1963, p. 309). The 1963 Chilean Christian Democratic platform advocated a mixed economy, control of foreign investment, agrarian reform, and government reform. In the international sphere, the Chilean Christian Democrats desire to cooperate with the United States. At the same time, they insist that Latin America should have a stronger voice in world affairs and a broader range of international relations. Further, they urge the Latin American nations to cooperate among themselves. Frei is endeavoring to expand Chilean contacts with Europe. Also, he supports Latin American economic integration and is urging the creation of a common market for all of Latin America.

Theory and philosophy. As noted earlier, a large measure of the Christian Democratic ideology is drawn from European sources. In addition to Frei, Latin Americans who have contributed to the ideology include Jaime Castillo, Jacques Chonchol, Julio Silva, Máximo Pacheco Gómez, Bernardo Leighton, Radomiro Tomic, and Rafael Caldera.

Castroism. On New Year's Day, 1959, the Batista dictatorship in Cuba collapsed and Fidel Castro came to power. The victors, who had waged a guerrilla war since December 1956, were determined that "this was to be a thorough-going revolution. The institutions and groups which possessed sufficient power to block such a revolutionary course were to be neutralized and, if necessary, destroyed. Above all, the United States was not going to be able to impose limitations upon change" (Schneider 1964, pp. 27–28). And for the first time

in Cuban history, a group of revolutionaries, after achieving power, began a full-scale social revolution instead of rewarding themselves with the spoils of government.

The program. A social revolution is a complex of actions. Only a few of the Cuban actions can be cited here.

The Agrarian Reform Law was passed just four months after Batista's fall. It had three objectives: to Cubanize and socialize the sugar industry, to give land to the landless, and to diversify agricultural production. The law provided for three types of holdings: state farms, sugar cooperatives (now scheduled to be converted into state farms), and small peasant properties. At present more than 70 per cent of the land is state owned.

Decrees during 1960 nationalized all large businesses, both Cuban and foreign. Since then additional businesses have been nationalized and a collective economy has emerged.

Beginning in 1962, emphasis was put on industrial expansion. However, after Castro's trip to Moscow in May 1963, Cuba accepted the principle of the international socialist division of labor, which led to a reversal of the revolution's original emphasis on agricultural diversification and industrialization (Hennessy 1964, p. 203). Now, as before 1959, emphasis is on sugar production.

Education has also received attention. An imaginative attack was made on adult illiteracy through the 1961 *alfabetismo* campaign. The public education system was reformed; teaching was nationalized; and private schools were suppressed. Emphasis in university education was placed on science and technology.

Evolution of Castroism. The Cuban revolution became a communist revolution. This statement is based on the view that "Castro was not a Communist for all practical purposes before he took power but decided to cast his lot with the Communists sometime afterward" (Draper 1965, p. 3).

Castro's "History Will Absolve Me" speech at his 1953 trial and the succeeding pamphlet provided the first insight into his objectives. He promised restoration of the 1940 constitution, a popularly elected government, and a relatively limited land reform program. "The most radical note in the speech . . . was perhaps a brief reference to the 'nationalization of the U.S.-owned electric and telephone companies'" (*ibid.*, p. 6). The "History Will Absolve Me" program was within the scope of traditional left-wing Cuban politics. The same judgment applies to the several pronouncements issued during the guerrilla war.

On December 2-3, 1961, Castro made his "I Am

a Marxist-Leninist" speech. The speech was preceded by a host of actions indicating an increasing closeness between Castro and the communist bloc. Relations between Castro and the Cuban communists had not always been cordial; in the early 1950s they were strained. However, after Castro gained power, the communists not only supported him but also gave him the assistance of their trained cadres. At the same time Castro was gradually alienated from his moderate supporters, who consistently called for a slowing down of his efforts to turn society inside out (Burks 1963, p. 82).

With the "I Am a Marxist-Leninist" speech, Castroism obtained an ideology or philosophy. In and of itself Castroism was an armed struggle, not an ideology, and Castro gave very little attention to developing one for the movement. Rather, the movement borrowed or attached itself to existing ideologies and could change attachments (although it may no longer be able to do so).

Castro's identification with Marxism-Leninism put the Cuban revolution in a very different category from the other Latin American movements and led Castro to adopt means different from those used by the other movements. It also affected Cuban relations with the outside world. The identification with communism and the declared intention of exporting Castro-style revolutions have, more than anything else, made the United States and many Latin Americans hostile to Cuba.

Theory and philosophy. The numerous speeches and articles of Fidel Castro and his closest associates are the best source of the ideas or ideology of Castroism. Many of the speeches and articles have appeared in the Cuban periodicals *Cuba socialista*, *Revolución*, *Hoy*, and *Verde olivo*.

This article has focused on movements for relatively sharp reform or revolution. A more comprehensive treatment of significant political elements and groups would include an analysis of elements supporting the *status quo*, even though these elements perhaps do not constitute "movements." Hopefully, however, the article shows both the essence and the variation of the major twentieth-century Latin American political movements. In a very real sense, the essence is far greater than the variation. Furthermore, the movements, in their goals as well as in their means, resemble those found in other developing regions, and even the diversity of movements found in Latin America is similar to the diversity found in the new nations of Asia and Africa.

The ideas embodied in the twentieth-century movements stand in sharp contrast with the bulk

of Latin America's nineteenth-century political thought. Nineteenth-century thought was nonindigenous, primarily imitative of European thought. The current movements are rooted in local social-economic-political conditions; hence, they are more realistic and practical as means of solving Latin American problems and restructuring Latin American society.

LAUDERDALE, JAMES MAITLAND

James Maitland, eighth earl of Lauderdale, (1759-1839) was a product of the famous Scottish educational system that flourished in the second half of the eighteenth century. He was a pupil of the great John Millar, of whom it was said that "to hear his lectures . . . students resort hither (i.e., to Glasgow) from all quarters of Britain." Among his contemporaries in Glasgow and Edinburgh Lauderdale numbered James Mill, Sydney Smith, Francis Jeffrey, Thomas Chalmers, Francis Horner, and Henry Brougham—to name but a few members of that amazing generation. Politically he allied himself with the Whig opposition to Pitt, a policy that long kept him from high government office, an honor he would without doubt have achieved had he been of the government party. Following his teacher he was a staunch defender of democratic principles at a time when the holocaust of the French Revolution encouraged an extreme reaction in England. However, it would be a mistake to place Lauderdale in the radical tradition; he advocated limited democracy, and he lived to oppose—in a rather inexplicable *volte face*—the moderate innovations suggested in the 1832 Reform Bill.

Lauderdale has a rightful place in the history of economics, although not perhaps as a major figure. This is a position comparatively recently achieved and is a consequence, as with so many reevaluations in the history of economics, of quite recent developments in economic analysis.

Lauderdale's most original contributions are to be found in his *Inquiry Into the Nature and Origin of Public Wealth* (1804). The frame of reference for this work is Adam Smith's *Wealth of Nations*,

and in an important sense Lauderdale's *Inquiry* may be regarded as a commentary on Smith's classic. It is important to remember this when considering Lauderdale's position in the development of economic thought. Lauderdale is often regarded as being in basic opposition to the orthodox English classical school and as representing an entirely separate, although contemporary, stream of development. While there is an element of truth in this, Lauderdale's work should not be considered too far outside the mainstream of economic thought: he did have certain criticisms of Smith's orthodoxy, but in terms of policy—the belief in the competitive order and the minimization of interference with economic systems—Lauderdale was part of the classical school.

The central theme of the *Inquiry*—the nature of relations between individual and public well-being—is not as pathbreaking as Lauderdale thought. He was worried by the fact that a rise in total spending on a commodity might be accompanied by a decline in the physical volume of purchases. We would now consider the problem in terms of index numbers of output. Lauderdale, however, was forced to consider it in terms of the demand schedule and what is now called the elasticity of the schedule, and did so in a way that was highly sophisticated for the time. His emphasis on the role of utility in the determination of relative prices places him much more with the subjective school (Condillac, Say, A. Walras, S. Bailey) than with the classical writers.

Lauderdale also applied his analysis to the question of overproduction. He argued, in opposition to the central classical position—often described as a belief in Say's Law—that saving could, nationally, be carried too far and result in an over-all excess supply of goods. It is for this reason that some contemporary economists, like Alvin Hansen or H. L. McCracken, consider Lauderdale as an early forerunner of Keynes. This is a mistaken view: since Lauderdale assumed the equality of *planned* saving and investment, oversaving was for him the mere production of capital equipment. This is certainly not what is normally understood as the Keynesian dilemma of capitalism. However, it must be acknowledged that when Lauderdale applied his analysis to the economic effects of national debt policy he came very close to a modern understanding of the question.

Lauderdale also wrote on monetary questions and gave an early statement of the bullionist position in *Thoughts on the Alarming State of the Circulation and on the Means of Redressing the Pecuniary Grievances in Ireland* (1805). Later on

he defended the Bullion Report—he was a member of the committee that prepared it—and pressed for the early resumption of cash payments. Rather paradoxically, he combined these orthodox monetary views with vivid fears of underconsumption.

LAUNHARDT, WILHELM

Carl Friedrich Wilhelm Launhardt (1832–1918) was by training and profession a transportation engineer, but he is now remembered chiefly for his pioneer work in the application of mathematical techniques to economic problems. He lived and worked virtually all his life in Hanover, Germany, as professor of highway, railroad, and bridge construction at the Polytechnical College. He received an honorary engineering doctorate in 1903 from the Institute of Technology at Dresden in recognition of basic work done on the technical and economic problems of transportation, in particular, of railroads. Not all his economic thinking was original, of course; on questions of capital and interest, for example, his ideas in general followed those of Léon Walras and Stanley Jevons. But he made important contributions to welfare economics, to pricing policies for public utilities, to industrial-location and market-area analysis, and to transportation-engineering economics in the narrow

sense, as well as doing original work on the labor-supply function (1885, pp. 88-97).

Welfare economics. Much of Launhardt's writing in the area of welfare economics, although embedded in price theory, often delves into side areas that anticipate recent developments. For instance, his treatment of "repeated exchange" and "exchange with continually changing prices" in its dependence on the number of market participants (1885, pp. 35-53) foreshadows the basic theme, if not the results, of Oskar Morgenstern's demand theory (1948) rather than being simply a version of Walrasian *tâtonnement*.

Knut Wicksell (1901) implied that Launhardt had supplied a pseudo proof of the proposition that pure, perfect competition leads to the greatest social income. However, Launhardt explicitly disagreed with this proposition; in fact, in criticism of Walras, he branded such a conclusion as a "grave error" (1885, pp. 27-33, 42-44).

Public utility pricing policies. Launhardt's analysis of railroad costing and pricing (e.g., 1885, pp. 189-205), while in the spirit of Walras and Jevons, has been acclaimed for its originality and clarity. His analysis is marred by the spurious definiteness that results from his assumption of specific function forms. He opposed private ownership of railroads, since he favored marginal-cost pricing and differential freight rates, and believed that overhead costs should be paid out of general taxation in a manner dictated by over-all fiscal policies. Similar studies had been done both by Jules Dupuit and by Émile Cheysson and Clément Colson. The latter two were contemporaries of Launhardt's and, like him, combined engineering with economics.

Industrial location and market area. In the words of Walter Isard (1956, pp. 143, 160), Launhardt "presented the first significant treatment of industrial location theory" and "the earliest systematic treatment of the division of the market-area among competing firms" (see Launhardt 1885, pp. 149-214). Although Johann Heinrich von Thünen had previously discussed industrial location, varying the circumstances more than Launhardt was to do, still Launhardt's location theories contain the germs of ideas later developed by Alfred Weber, Tord Palander, and more recent theorists. For example, he sketched the pole principle: a geometric construction for finding locational equilibrium points (Isard 1956, pp. 254-287). In the Launhardt-Hotelling problem, however, Launhardt did not simultaneously vary price and location; that remained for Harold Hotelling (1929) to do.

Transportation-engineering economics. In the field of transportation-engineering economics, which lay closer to his main occupation, Launhardt investigated such matters as the influence of gradients and curves on railroad operating costs (1877) and the location-dependent "rentability" of highways and railroads.

LAW

The articles under this heading deal mainly with the study of law, and with the relationship between law and society, as do also JURISPRUDENCE; LEGAL REASONING; PSYCHIATRY, article on FORENSIC PSYCHIATRY; PUBLIC LAW. The articles listed under LEGAL SYSTEMS discuss and compare the major modern systems. Other branches of the law are dealt with in ADMINISTRATIVE LAW; CANON LAW; CRIMINAL LAW; CONFLICT OF LAWS; CONSTITUTIONAL LAW; INTERNATIONAL LAW; MILITARY LAW. The creation of law and its relations with political institutions are discussed in ADJUDICATION; CONFLICT OF INTERESTS; JUDICIAL PROCESS; JUDICIARY; LEGISLATION; POLITICAL JUSTICE. Relevant to the development of modern jurisprudence are the biog-

raphies of AUSTIN; BLACKSTONE; BRANDEIS; CARDOZO; COKE; DUGUIT; EHRLICH; FRANK; GIERKE; GROTIUS; HAMILTON, WALTON H.; HAURIUO; HOLMES; JELLINEK; KANTOROWICZ; KELSEN; LLEWELLYN; MAINE; MAITLAND; MOORE; JOHN BASSETT; POUND; RADERUCH; SAVIGNY; SCHMITT; VATTEL. For a discussion of law and related problems in preliterate societies see POLITICAL ANTHROPOLOGY; SANCTIONS.

THE SOCIOLOGY OF LAW

The broad aim of legal sociology is the extension of knowledge regarding the foundations of a legal order, the pattern of legal change, and the contribution of law to the fulfillment of social needs and aspirations. The special interest of sociology in these matters rests on the basic assumption that law and legal institutions both affect and are affected by the social conditions that surround them.

Within sociology, the study of law touches a number of well-established areas of inquiry. In criminology attention is given to the changing character of penal law, the assumptions upon which it rests, and the social dynamics of law enforcement and corrections. The sociology of law shares with political sociology a concern for the nature of legitimate authority and social control, the social bases of constitutionalism, the evolution of civic rights, and the relation of public and private spheres.

The roots of legal sociology lie mainly in jurisprudence rather than in the autonomous work of sociologists. In legal theory a "sociological school" emerged out of the work of such jurists as Rudolf von Jhering, Oliver Wendell Holmes, Léon Duguit, Eugen Ehrlich, and Roscoe Pound, all of whom felt the need to look beyond the traditional confines of legal scholarship. The sociologists Émile Durkheim, Max Weber, E. A. Ross, and W. G. Sumner, among others, contributed to the development of a sociological orientation among students of jurisprudence, in some cases by direct influence on legal writers such as Duguit and Pound.

Historical perspectives

Four basic motifs have been prominent in the intellectual history of legal sociology: historicism, instrumentalism, antiformalism, and pluralism.

Historicism. Historicism emphasizes the tracing of legal ideas and institutions to their historical roots; patterns of legal evolution are seen as un-

planned outcomes of the play of social forces. Important illustrations of this approach are Henry Maine's *Ancient Law*, Oliver Wendell Holmes's *Common Law*, and the treatments of legal typologies and evolution in Émile Durkheim's *Division of Labor in Society* (1893) and various writings by Max Weber (see especially 1922a). The historicist emphasis has had two implicit objectives. First, historical study is a way of identifying legal anachronisms, especially in the reasoning behind a received rule or concept. Second, the analysis of an underlying historical trend (e.g., Maine's thesis regarding the movement of "progressive societies" from status to contract) can provide an illuminating context for the interpretation of contemporary issues.

Instrumentalism. The instrumentalist approach, associated with the names of Jeremy Bentham and Rudolf von Jhering, among nineteenth-century writers, as well as Roscoe Pound, calls for the assessment of law according to defined social purposes. It thus invites close study of what the law is and does in fact. The chief significance of instrumentalism is that it encourages the incorporation of social knowledge into law. For if laws are instruments, they must be open to interpretation and revision in the light of changing circumstances. Moreover, law is seen as having more than one function; not only is it a vehicle for maintaining public order and settling disputes, but it also facilitates voluntary transactions and arrangements, confers political legitimacy, promotes education and civic participation, and helps to define social aspirations.

Antiformalism. Sociological jurisprudence has gained much of its vitality from attacks upon the "unrealistic" nature of legal rules and concepts. A jurisprudence that emphasizes the purity of law as a formal system is fallible on two counts. First, legal rules are necessarily abstract and general; there is always a considerable gap between a system of general rules and its implementation, if only because the rules are applied by human agencies that have their own interests and problems. Second, any view of the legal order as an isolated system wrongly detaches it from the environment in which it is implicated. Failure to take account of the historical and cultural forces impinging upon the law not only distorts reality but gives the legal order an excessive dignity, insulates it from criticism, and offers society inadequate leverage for change. In pressing its criticism of legal abstractions, the antiformalist approach leads readily to a derogation of the importance and effectiveness of legal norms.

While antiformalism is congenial to an instru-

mentalist assessment of the legal tradition, it is out of sympathy with the more narrowly utilitarian image of man as an isolated, goal-seeking actor guided by a hedonic calculus. Instead, it encourages a fuller awareness of the *nonrational* springs of action, of human dependency on social support, and of the emergence of social systems that have a viability of their own. The antiformalist theme is prominent in the work of Eugen Ehrlich and of the American legal realists, but almost every analyst of the social or psychological foundations of law has struck the same note, albeit with varying emphasis.

Pluralism. In the history of legal sociology, "pluralism" refers to the view that law is located "in society"—that is, beyond the official agencies of government. Sociological skepticism of state law has led some legal scholars, notably Ehrlich, to deny that law is solely or even mainly made by government. Ehrlich held that law is endemic in custom and social organization; it is in the actual regularities of group life that we find the "living law." In context, this approach is more than an appeal to bring law into closer relation with social practice; it is an assertion that *authoritative* legal materials are to be found in the realities of group life. In other words, it questions the claim of the state to be the sole receptacle of legal authority.

The pluralist motif was further enhanced by the central place Ehrlich gave to the "inner order of associations" as a font of law; here his work recalls Otto von Gierke's treatment of the law of associations. Gierke stressed the reality of the autonomous collectivity, and in doing so he criticized not only the atomistic view of society and legal order as based upon individual will but also the legal notion of the association as a juridical fiction. Related ideas are found in the writings of Maurice Hauriou, who sought a legal reality in "the institution"—that is, in the association or enterprise (private as well as public) that has its own established authority and appropriate procedures.

The sociological approach. These intellectual tendencies have helped open up the boundaries of the legal order. They have enlarged the relevance of nonlegal ideas and findings to law and legal reasoning. On the other hand, they have had the common outcome of downgrading formal legal systems as significant social realities. In an important sense, the sociological school has been anti-legal. It has sought to put law in its place by emphasizing the primacy of the social context and by seeking "the legal" outside of its conventional sphere. In so doing, the sociological perspective runs the risk of dissolving the concept of law into the broader concepts of social control and social

order; the idea of a "living law," encompassing all the regularities of group life, offers no touchstone for the distinctively legal. Whatever the merits of the sociological school in having called attention to the need for a more realistic jurisprudence, the failure to offer a theory of the distinctively legal has been its cardinal weakness.

The distinctively legal

According to Max Weber, the distinctively legal emerges when "there exists a 'coercive apparatus,' i.e., that there are one or more persons whose special task it is to hold themselves ready to apply specially provided means of coercion (legal coercion) for the purpose of norm enforcement" ([1922a] 1954, p. 13). In other words, a legal norm is known by the probability that it will be enforced by a specialized staff. Thus Weber offers an operational definition of law that is meant to exclude all value judgments in the assessment of what is or is not law. Although he emphasizes coercion, Weber is careful to point out that the threat of physical force is not essential to legal action, for coercion may consist in the threat of public reprimand or boycott. Thus Weber's definition does not limit law to the political community; it allows for "extrastate" law, such as ecclesiastical law or the law of any other corporate group that is binding on its own members.

Weber's approach does have a certain rough utility, and it has the special virtue of being general enough to encourage the study of law in private associations. However, he offers no satisfactory theoretical ground for identifying the requirements of a legal order as he does. The availability of a specialized staff for the enforcement of norms may be highly correlated with the existence of a legal order and thus may serve as a reliable *indicator* of norms that have been selected for special treatment. However, it does not follow that this is what basically distinguishes legal from nonlegal norms and institutions.

Authoritative norms. An adequate theory of law must identify the distinctive *work done* by law in society, the special *resources* of law, and the characteristic *mechanisms* that law brings into play. In the quest for such a theory, little is gained from formulas that place coercive enforcement of norms at the center of legal experience. The key word in the discussion of law is *authority*, not coercion. The fundamental problems of jurisprudence stem from the puzzles and ambiguities associated with identifying the sources of authoritative rules, the authoritative application of rules, and the nature of authoritative change in existing rules.

Although the legal requirement of paying a tax certainly has some connection with the coercive consequences of refusal to pay, the character of the obligation is more decisive. A tax is *illegal* if it violates an authoritative order, and it is *nonlegal* if it lacks appropriate authority, regardless of whether the probability of coercion exists. Hence legality presumes the emergence of authoritative norms whose status as such is "guaranteed" by evidence of other, consensually validated, rules.

H. L. A. Hart has argued that, in stepping "from the pre-legal to the legal world," a society develops special rules for curing the defects of a social order based on unofficial norms (1961, p. 91). A regime of unofficial norms has a number of inherent limitations, including the difficulty of resolving uncertainties as to the existence or scope of a norm. No criterion or procedure is available for settling such issues. The distinctively legal emerges with the development of "secondary rules," that is, rules of authoritative determination. These rules, selectively applied, raise up the unofficial norms and give them a legal status.

The elementary legal act is this appeal from an *asserted* rule, however coercively enforced, to a *justifying* rule. This presumes at least a dim awareness that some reason lies behind the impulse to conform; furthermore this reason is founded not in conscience, habit, or fear alone but rather in the decision to uphold an authoritative order. The rule of legal recognition may be quite blunt and crude: The law is what the king or priest says it is. But this initial reference of a historically given social norm to a more general ground of obligation breeds the complex elaboration of authoritative rules that marks a developed legal order.

Resources of legal institutions. The special work of law is to identify claims and obligations that merit official validation or enforcement. This may consist of nothing more than the establishment of a public record invested with a special claim upon the community's respect as a guide to action. When institutions emerge that do this work we can speak of a legal order. These institutions need not be specialized, and they may have no resources for coercive enforcement; it is essential only that their determinations affecting rights and duties are accepted as authoritative.

An authoritative act asserts a claim to obedience, and the reach of that claim determines whether and to what extent a legal system exists. Although a weak legal order rests on a narrow base of consent, it may be able to mobilize very large resources of intimidation and thus command wide, if grudging, submission. A strong legal order

is the product of a more substantial consensus and summons more willing obedience; it is correspondingly less dependent on the machinery of coercion. There is thus an important difference between the strength of a *regime* and the strength of a *legal order*, although the sheer persistence of the former may greatly influence acceptance for its claim to speak with authority. Of course, coercion is an important and often indispensable *resource* for law, but so are education, symbolism, and the appeal to reason. Coercion does not make law, though it may indeed establish an order out of which law may emerge.

In much of his work Max Weber saw quite clearly the intimate relation of the legal and the authoritative. For example, his theory of authority and legitimacy contrasts the charismatic, the traditional, and the "rational legal," thus placing law in a context of evolving forms of authority (1922b, pp. 328 ff. in 1947 edition). In this analysis Weber views fully developed law as a system of governance by rules; he sees the distinctively legal obligation as a component of an impersonal order that exhibits a strain toward rationality. Thus when Weber actually used the concept of law, especially in his theory of bureaucracy, he greatly modified the significance of coercion.

Social foundations of legality

The view of law just sketched highlights the place of authority, consensus, and rationality in the legal order. In a developed legal order, authority transcends coercion, accepts the restraints of reason, and contributes to a public consensus regarding the foundations of civic obligation. To the extent that law is "the enterprise of subjecting human conduct to the governance of rules" (Fuller 1964, p. 106), it can be said that law aims at a moral achievement; the name of that achievement is *legality* or "the rule of law." Its distinctive contribution is a progressive reduction of the arbitrary element in positive law and its administration.

As an intellectual discipline, the sociology of law has a far broader compass than the study of "the requirements of justice which lawyers term principles of legality" (Hart 1961, p. 202). Not every society gives equal weight to the ideal of "control by rule" as against other ideals; and there is much else to be said about law in society. Still, law is so intimately associated with the realization of these special values that study of "the rule of law" must be a chief preoccupation of legal sociology. Indeed, a considerable amount of contemporary research, as we shall note below, falls within this topic.

The sociological study of legality presumes that the potential of law for realizing values is at best unevenly fulfilled. Legal decision making is carried on by living men in living institutions, who are subject to all the external pressures and constraints and all the inner sources of recalcitrance that frustrate the embodiment of abstract ideals in action. At the same time, some patterns of group life are more congenial than others to the rule of law. To discover which social conditions are congenial to the rule of law and which undermine it, and in what ways, is the main task of scientific inquiry in this field. Four topics provide a framework in which research on legality can be pursued: the transition from legitimacy to legality; rational consensus and civic competence; institutionalized criticism; and institutionalized self-restraint. While these topics are suggested by the experience of the Western world, their relevance is universal.

Legitimacy and legality. The existence of legality presumes that the power exercised by public officials is "legitimate" power. This means that an appeal is made to some principle as a source of right—the right to dispose of community resources in a certain way and especially the right to issue orders and enforce them. Many different principles of legitimacy are possible—for example, divine will, democratic election, private property, hereditary succession, seniority, and special competence. What principle of legitimacy will be accepted depends on the nature of the group, its cultural heritage, and special historical circumstances. To trace the rise and decline of various principles of legitimacy is to touch on major themes of political and social history.

Legitimate power tends to be restrained. It is inherent in legitimacy that the will of the ruler, including the majority will of a democratic assembly, is not completely free. Nevertheless, many regimes properly classified as legitimate retain a very large amount of arbitrary rule. Legitimacy is only a first step toward legality. It can begin in a quite primitive fashion, meaning little more than unconscious acceptance of another's authority because he is thought to have communication with the gods or special magical powers or because he belongs to a noble family. Authority is primitive when power is legitimated by no more than a historically given public sentiment supporting a claim to rightful rule.

But legitimacy carries the lively seed of legality, implanted by the principle that the exercise of power must be justified. From this it is but a step to the view that reasons must be given to defend

official acts. Reasons invite evaluation, and evaluation requires the development of public standards. At the same time, implicit in the fundamental norm that reasons should be given is the conclusion that where reasons are defective, authority is to that extent weakened and even invalidated.

The transition from legitimacy to legality requires the recognition that official acts can be questioned and appraised. The test is not whether the ruler is wise or good but whether his acts are justified by an explicit or implied grant of power. Most important, *legality goes beyond a gross justification of the right to hold office*; it gains strength and focus in proportion as the criterion of legitimacy is used to decide whether particular acts meet public standards of validity. For example, if conservation of natural resources is the purported foundation of rule making by a government agency, then that publicly acknowledged objective becomes available as a basis for criticizing specific rules and decisions.

Clearly some principles of legitimacy are more competent than others to sustain the ideal of legality. If power is justified on the basis of tradition, proprietorship, kinship, or hereditary succession, it is difficult to find the leverage for continuous, reasoned criticism. When prescriptive right gives way to an abstract principle, as in the case of justification by popular will, social utility, trusteeship, or even divine right, then the principle of legitimacy can be analyzed and acts assessed. The way is then open for an appeal to reason.

Rational consensus and civic competence. Legality requires that the principles of legitimacy be firmly established in the community's habits of thought; hence the study of both the content and the *quality* of consensus has a special bearing on the social bases of the rule of law. Strictly speaking, there can be no purely rational consensus. However, it may be approximated under two related conditions: if the historically given, non-rational sentiments are themselves supportive of rational conduct, for example, when received modes of apprehending man and society encourage self-restraint and tolerance of ambiguity; and if there is broad opportunity for the emergence of a public opinion founded in the free play of interests and ideas. In other words, rational consensus presupposes a genuine public opinion rather than agreement based on manipulation, withholding of information, or unmitigated appeals to tradition.

Whatever contributes to rational consensus provides social support for legality. Decision making in the light of legality requires the continuous

exercise of discriminating judgment, especially in the balancing of values, the elaboration of defensible rules, and the application of abstract principles to changing circumstances. While this work is largely carried on by a relatively small group of professionals, the capacity of the professionals to sustain and extend the ideals of legality depends on a parallel development of the public mind. The legal profession itself is not immune to influences that may undermine its commitment to the rule of law.

The consensus that sustains legality entails deepened public understanding of the complex meaning of freedom under law. This goes beyond passive belief or even commitment. It is an extension of civic competence—the competence to participate effectively in a legal order. This is manifested, for example, in an increased capacity to be patient with procedural niceties in the face of a desire to punish, to exercise impartial judgment, and to use principles of criticism against even the most favored leaders of government.

In a vital legal order something more is wanted than submission to law. A military establishment places very great emphasis on obedience to lawful commands, yet such a setting is hardly a model of the development of legality. So, too, a conception of law as the manifestation of awesome authority encourages a posture of submission and is fully compatible with arbitrary rule. In a community that aspires to a high order of legality obedience to law is not submissive compliance. The obligation to obey the law should be closely tied to the defensibility of the rules themselves and of the official decisions that enforce them.

Institutionalized criticism. If the ideals of legality are to be fulfilled, the capacity to generate and sustain reasoned criticism of the rules and of official discretion must be built into the machinery of lawmaking and administration. To this end, the Anglo-American legal tradition has relied heavily upon the availability of counsel, upon the adversary concept of the legal process, and upon the freedom of the judiciary and other officials to adopt a critical stance toward received law, both statutory and judge-made.

Sociological research in this area confronts the ideals of due process with the realities of institutional life. For example, the availability of counsel may be limited for large sectors of the population; the independence and objectivity of officials may be weakened by their social origins and commitments; and limitations of competence and resources may inhibit the judiciary from effective criticism

of rule making in private and public agencies. The possibility of effective criticism may largely depend upon the availability of group resources. The lone individual seeking justice—especially if he is poor and if his claim is subject to routine processing—has little opportunity to press for new interpretations of law or of administrative regulations. Group-based counsel, on the other hand, can develop specialized expertise as well as work out a strategy for legal change.

In the Anglo-American tradition, the adversary principle has a special place as a vehicle of institutionalized criticism. It lends legitimacy to partisan advocacy within the legal process, allowing and even encouraging the zealous pursuit of special interest by means of self-serving interpretations of law and evidence. The assumptions underlying the adversary principle have not been fully analyzed or tested, nor have variations or functional surrogates in other societies been adequately studied. Moreover, there is evidence that partisan advocacy is weakened by certain factors that are becoming increasingly common in "administered" societies. Among these are the commitment of tribunals to a positive outcome, as in family conciliation proceedings, reliance on experts and investigators who serve the court directly; the mandate to temper justice with treatment, as in juvenile hearings; and the routine handling of a large number of cases.

No doubt these new problems and contexts will lessen reliance on the adversary principle in some areas; more important, however, will be the development of new forms of advocacy and critical dialogue. Administrative agencies, both criminal and civil, are increasingly recognized as active centers for making laws and dispensing justice, although the visibility of such decisions is often quite low. Sociological study of organizations can trace the actual course of decision making and can identify the opportunities available, within the social structure of the agency, for increasing the visibility of decisions and developing new forms of institutionalized criticism.

Institutionalized self-restraint. Every officer of the law—policeman, president, legislator, attorney, judge, licensing commissioner, draft board member—is in some degree a magistrate. He exercises discretion and thereby affects the rights of citizens. The rule of law requires that this discretion be restrained, yet it also asks for independent judgments in the assessment of fact, the assignment of moral culpability, and the application of legal rules to particular circumstances. To achieve re-

strained discretion, more is needed than criticism of authority and pressure upon it. The system depends heavily on *self-restraint* and thus on social mechanisms for building in appropriate values and rules of conduct.

Historically, legal self-restraint has been supported by public consensus on the nature and limits of authority, professionalization of lawyers and other officials, and the evolution of clearly defined roles, such as that of the judge. But there is considerable variation in that achievement, and under modern conditions there is a need for more attention to the *organizational* sources of self-restraint as distinguished from mechanisms of socialization. Ethical conduct is mainly found in settings that nourish and sustain it, that is, where such conduct makes sense for the official in the light of the realistic problems he faces. To design such settings is properly the chief aim of the architect of legal institutions. As applied to the legal profession, this principle has been documented in a recent study of the New York City bar (Carlin 1966).

Law and social change

The preceding discussion of the social foundations of legality emphasizes the conditions that strengthen or weaken the rule of law. The same problem may be approached historically, placing the evolution of legality in a context of broad social change and relating it to the development of other social institutions, including culturally defined conceptions of authority and justice. Thus Max Weber was interested in the emergence of rationality as a principle of organization and decision making; he saw rationality as the key to modernization and traced its effects in many fields, including law.

In modern Western society the extension of legality to new institutions and settings occurs mainly *within* government, encompassing wider circles of officials and agencies, subjecting more decisions to review, and raising the standard of what constitutes fair procedure. The Scandinavian ombudsman, an official to whom the citizen can appeal directly when he feels wronged by a government agency, is a symbol of the demand for new modes of redress against a large and opaque government apparatus. Also evident is a tentative movement toward legal restraint of arbitrary decision in nongovernmental institutions, especially those that serve a general public, such as colleges, trade unions, and large business firms. These developments, fostered in large measure by the work

of associations formed to advance group interests, reflect a growing public sensitivity to legal rights. The legal profession itself, both by scholarship and by the official statements of its professional organizations, has contributed to the critical assessment of official procedures. Nor should it be overlooked that modern organizations, as part of their greater effectiveness and rationality, have an increased capacity to support the machinery of due process.

There is, however, an underlying conflict between administration and legality. In the first place, procedural safeguards are costly in time, energy, and the risk that action will be inhibited. In the United States, for instance, the police must carry out their traditional tasks of surveillance and apprehension subject to many new legal rulings affecting search, arrest, and detention. Any organization that has a job to do, yet must meet standards of fairness, faces this tension. Second, an official who is preoccupied with the fair application of general rules—equal treatment under law—finds it difficult to deal with each problem or case on its merits, taking account of special circumstances and needs and adapting policies to desired outcomes. The modern quest, and one that requires much supportive research, is for variable standards of fairness, embodying basic principles of procedural justice with due regard for the distinctive needs of specialized institutions and programs.

Incipient law. The antiformalist posture of legal sociology has encouraged interest in the problem-solving practices and spontaneous orderings of business or family life. While this approach has tended to depreciate formal law, in principle it just as easily supports an emphasis on the *emergence* of formal law out of the realities of group life. Incipient law is implicit in the way in which public sentiment develops or in any increasingly stabilized pattern of organization; it refers to a compelling claim of right or a practice so viable and so important to a functioning institution as to make legal recognition in due course highly probable. Thus some of the private arrangements worked out in collective bargaining agreements, especially seniority rights and protection against arbitrary dismissal, may be seen as incipient law. However, the location of incipient law cannot rest solely on the prevalence of a practice or even the urgency of a claim; two parallel assessments are required. First, the social viability of the practice in question—its functional significance for group life and especially for new insti-

tutional forms—must be considered. Second, the contemporary evolution of relevant legal principles must be assessed to see whether the new norm can be absorbed within the received but changing legal tradition.

A focus on incipient legal change bridges the concepts of law and social order without confounding the two; it assumes that law does indeed have its distinctive nature, however much it may rely on social support or be responsible to social change. On the other hand, some law is seen as *latent* in the evolving social and economic order. For example, the trend toward strict liability for harm caused by defects in manufactured goods (weakening or eliminating the need to prove negligence) reflects changing technology, both in manufacture and distribution, as well as the increased capacity of large firms to absorb the attendant costs either by increasing productivity or by passing them on to the general public. Similarly, the growing importance of large-scale organizations carries with it the likelihood that new claims of right will emerge, based upon a new perception of organizational membership as a protectable status.

Law as a vehicle of social change. For the most part, legal sociology has viewed law as a passive rather than active agent in social change. Law "responds" to new circumstances and pressures. However, especially in recent years the great social effects of legal change have been too obvious to ignore. The question is no longer whether law is a significant vehicle of social change but rather *how* it so functions and what special problems arise.

One way of approaching these problems is to consider the relative significance for social change of *legislation*, *administration*, and *common law*. Each has its special competence, and each has been dominant as a mode of change at different periods and in different branches of the law. In this context "common law" is not restricted to the Anglo-American legal tradition. Rather, it refers to any pattern of legal decision and evolution that relies on judicial creativity. Although this form of legal development is most explicitly recognized in what are called the "common-law" jurisdictions, in fact such creativity is inherent in the judicial process and plays an important part in the "code" jurisdictions of continental Europe (Friedmann [1944] 1960, pp. 483-486).

The common-law approach relies heavily upon tradition and the authority of the tribunal as sources of legitimacy. Judicial elaboration of abstract ideas, including reasoning by analogy, fits

new departures into a received system of concepts and rules. "Realist" criticism of common-law concepts has sometimes overlooked this social function of abstractions. Legal ideas are indeed often distant from the realities of social practice, but their very generality is useful for making new adaptations while preserving a sense of continuity and therefore of legitimacy.

The common-law method of change is mainly piecemeal and gradual. It can safeguard a precarious consensus by avoiding radical or sweeping change and by relying on studied indirection rather than unambiguous confrontation. On the other hand, judges who have the authority to interpret a basic statute, such as a written constitution, can provide leadership in some branches of the law, as United States history has shown. In such a case, public commitment to the statute reinforces the legitimacy of judicial decision.

The great weakness of common-law empiricism is the difficulty of working out comprehensive attacks on new problems, such as urban land use, industrial accidents, or labor-management relations. The common-law approach seems to work best when basic policy is settled and the need is for refinement of distinctions and adaptation of the policy to new settings.

Legislation is the most obvious way of bringing political will to bear for the purpose of effecting social change through law. Unlike courts, which are tied to tradition, legislatures are commonly perceived as legitimate agencies for innovation; they can muster better means of inquiry, and they can create administrative agencies to execute and elaborate legislative policy.

There are important continuities, as well as tensions, in the relation between legislation and common law. Where these continuities and tensions occur, jurisprudential problems of law and social change arise. For example, a series of statutes can be viewed as creating a new "field" of law (such as labor law or welfare law), with the result that authoritative concepts and doctrines emerge which go beyond the letter of the statutes and form starting points for legal reasoning. This work of interpretation and elaboration, using a common-law perspective, is carried on by administrative agencies as well as courts. Its effect is to institutionalize the statutory policy.

Although politics and legislation are the basic sources of legal change in modern society, the administrative agency is a characteristic and potent *vehicle* of that change. It can summon material and human resources, including moral dedication and professional zeal, for turning legislative

policy into social reality. An administrative agency can contribute to law by detailed rule making, its own adjudications, the patterned course of discretion it adopts, the practical effect it has on the social structure, and the initiative it may take in proposing statutory changes. However, agencies differ markedly in their capacity to influence law and society. Much depends on whether the agency conceives of itself as active or passive; this in turn reflects the nature of its special constituency, if any, as well as the newness and popular appeal of the program, the initial resources it is given, and the relations it may develop with other agencies. Some agencies are captives of their constituencies, including groups they are supposed to regulate, and contribute little to legal development.

Perhaps the most basic resource of the law for fostering and guiding social change is the set of legal principles that can be invoked to justify action in their name. This is especially true of constitutional principles that contain ideals of civic right. Such ideals are usually only imperfectly embodied in the operative rules of a given time and place. For long periods the gap between the legal ideal and the legal reality may be accepted with passivity and even good will, but social change may bring with it new opportunities for more perfect embodiment of the ideal in practice and a quickened awareness of this possibility. The result is twofold: Energy for social change is enlarged by a sense of legitimacy, and those who attempt to defend the *status quo* are made vulnerable and placed on the defensive. Thus law both contributes to rising expectations and may, in due course, provide vehicles for their realization.

Major trends. Several large-scale social changes have contributed to a vast increase in the tasks that must be assumed by a modern legal order. As kinship, fixed status, and community have declined as sources of social control, the drift has been toward a mass society marked by high rates of mobility, fragmented social experience, rising demands for short-run gratification, and more active participation by large numbers in hitherto insulated areas of social life. This trend has resulted in greatly increased pressure on formal agencies of regulation and service. A related development has been the emergence of the large organization as the representative institution of modern society; it depends upon, and also summons, mass participation in economic, political, and cultural life. A new "corporatism" brings with it many new problems for the law, including assessment of the social responsibilities of private associations, blurring of the distinction between

private and public law, concern for the rights of association members, and regulation of competition and conflict when self-governing market mechanisms break down (Friedmann 1959).

A third significant trend has been the ascendancy of social interests over parochial interests. The increasing interdependence of existence in modern society and correlative changes in values have weakened the claims of private interests and stimulated the quest for criteria of social worth. This is the foundation of what has been called the "socialization of law." As described by Pound (1959), the socialization of law is manifested in a growing tendency to impose limitations on the use and disposition of property, on freedom of contract, and on the power of creditors to exact satisfaction; in the movement toward liability without fault; and in many other legal rules and concepts. While this trend undermines the concept of the individual as a holder of abstract rights, it tends strongly to make the *person* an object of social and legal concern. This is reflected in much welfare legislation, which often begins as a way of solving a social problem and increasingly turns attention to the needs of persons.

Social research

Recent efforts to encourage the sociology of law have emphasized the need for empirical research and for a corresponding sense of relevance to contemporary social problems. The newer work is less interested in showing the limitations of law relative to other forms of social control than in bringing the expertise of social science to bear on the analysis of specific problems. It is likely that in the future legal sociology will be characterized by an affirmation of law rather than by a downgrading of it. This is especially true of research on the administration of justice. Studies of tribunals and other legal agencies may be narrowly concerned with efficient use of scarce resources, but they also tend to compare the ideal and the reality. As the "morality of law" (Fuller 1964) becomes a subject for empirical research, there will be a natural tendency to stress the contribution law can make to a moral order.

In line with this emphasis, much current research centers on social aspects of the administration of justice, as in studies of the jury (Kalven & Zeisel 1966; Simon 1967), patterns of law enforcement (Lindesmith 1965; Skolnick 1966), juvenile justice (Tappan 1947; Matza 1964), and the legal profession. Most of this work is normative as well as factual: It seeks out the conditions and processes that undermine or support proce-

dural fairness and the recognition of basic rights. There is an implicit demand for fulfillment of legal ideals.

A more ambiguous attitude toward the moral significance of law is found in the sociology of deviance. Here the recent emphasis is on the law's role in *creating* deviance (Becker 1963). This occurs in two ways. First, the definition of what is "criminal" is a social process; and in borderline crimes, where consensus is weak, large numbers of people may find themselves classified as "criminals" as a result of political action by moralists. When this occurs, there is a strong tendency for illicit activity to continue, for that activity to take on more determinate criminal form, and for the quality of law enforcement to suffer. Second, a casual offender may be transformed into a committed deviant by the legal "processing" to which he is exposed, especially when he is systematically treated as a deviant and stigmatized as such. Under these circumstances law breeds illegality. The normative lesson is: To preserve the integrity of law it should be used with restraint in the control of personal conduct, especially where the specific harm is problematical and may be exceeded by the social costs of ineffective enforcement (Schur 1965).

Other research includes studies of public opinion and law (Cohen et al. 1958), legal forms and economic realities (Berle 1959; Macaulay 1963), judicial values and perspectives (Schubert 1960), the extension of legal or quasi-legal rights to members of "private governments," such as the large corporation (Eels 1962), and social history of legal ideas and institutions (Friedman 1965; Hall 1935; Hurst 1950; 1960; 1964). The comparative study of law and society is being stimulated by scholarly interest in the "developing" nations (Anderson 1963; Lev 1965), by the assessment of changes in communist society (Berman 1950; Hazard 1953; 1960), and by a marked tendency among some students of comparative law to take fuller account of social and political contexts (Von Mehren 1963).

The major problem of legal sociology remains the integration of jurisprudence and social research. Unless jurisprudential issues of the nature and functions of law, the relation of law and morals, the foundations of legality and fairness, and the role of social knowledge in law are addressed by modern investigators, the sociology of law can have only a peripheral intellectual importance.

II

THE LEGAL SYSTEM

The comparative analysis of the social structures of legal systems has its historical roots in the study of comparative law. It is possible to draw an analytical distinction between the two disciplines. Comparative structural analysis is a sociological endeavor. Its subject matter is the organization of legal activity and the variable character of the groups and social roles involved in the legal process; its primary goal is the discovery and explanation of regularities in institutional structure and development. Comparative law, on the other hand, is a jurisprudential study. Its practitioners are interested in the normative content of various systems of law and are often motivated by a desire to seek the fairest and most effective means of ordering the legal relations between men. Nevertheless, the intimate connection between the two fields should not be overlooked. In one branch of comparative law the sociological element is particularly strong: students of comparative legal history have generally accepted the proposition that legal concepts and modes of legal thought reflect an underlying framework of social organization. Thus, legal historians have often viewed the normative content of law from a sociological perspective.

Origins of the structural approach

The sociological perspective is at least as old as the Enlightenment and Montesquieu's classic, *De l'esprit des lois* (1748). Montesquieu found the sources of law in climate and geography and in the social institutions and national character of a people.

The concept of national character pervades the work of Friedrich Karl Savigny, who is generally

regarded as the founder of historical jurisprudence (Stone [1946] 1950, chapter 18). Savigny wrote in the context of a national debate regarding the proposed codification of German law. He argued that codification would destroy the peculiarly Germanic character of German law and that the loss of national distinctiveness would be disastrous because any system of law must truly reflect the spirit and genius of the institutions of a people. To document his views, he produced a series of scholarly volumes on Roman and German law that were designed to demonstrate the close correspondence between social and legal development in those nations.

From here it is but a short, logical step to our contemporary interest in the relation between the "positive" norms of the law of the state and the *de facto* norms which emerge from the institutions of the larger society. In American sociology this concern has independent roots in William Graham Sumner's interest in the mores, the folkways, and the stateways (1906), and in E. A. Ross's emphasis on social control (1901; see also F. J. Davis et al. 1962, chapters 1, 2). On a global scale, however, the dominant transitional figure was the Austrian jurist Eugen Ehrlich (1913).

The proposition that laws *ought* to reflect the peculiar character of a nation's social institutions is easily transformed into the closely related view that such a correspondence is desirable but has not been achieved. Ehrlich became disturbed by the failure of the conceptual apparatus of positive law to adequately reflect the "living law." For Ehrlich the living law is the *de facto* normative pattern that develops as competing social interests are resolved within the many groups and institutions constituting the "inner order" of a society.

In the English-speaking world the works of Sir Henry Sumner Maine (1861) had a profound impact on jurists and social scientists alike, since Maine attempted to trace both the evolutionary development of legal concepts and the social developments that produced them. Maine's posthumous influence extended to the Continent, where it played a role in shaping the thought of scholars within the emerging discipline of sociology.

Weber's comparative studies. Among those Continental scholars, Max Weber (1922) formulated the most comprehensive accounts of comparative legal structure. Weber's investigations were carried out as a part of his inquiries into the causes and consequences of the "rationalization" of the Western world. "Rationalization" in this context refers to the process by which an institution becomes systematically and logically elaborated ac-

cording to general, analytical, and calculable principles.

Weber developed one of his characteristic ideal typologies for distinguishing the various types of legal thought found in the history of juristic development. He then elaborated one of Maine's fundamental ideas by showing that each type of legal thought is associated with a given form of legal organization and particularly with the structural location of legal specialists. Thus, for example, the logical rationality of Continental European conceptual jurisprudence is attributable to the influence of university-based professors who turned their philosophically trained intellects to the task of expounding the Roman law as a logically closed, abstract system.

Weber also examined the impact of variation in the structure of both governmental institutions and power relations among elite groups. He pointed out that the forms of legal development fostered by the university-based Romanists appealed to the interests of monarchs and bureaucrats in systematic administration and to the concerns of the rising capitalist class with the predictable protection of private rights.

Weber's account of comparative legal structure must also be seen in the context of his general interest in the rise and development of capitalist economic structure. His analysis of the role of law in capitalist development is effectively summarized in his treatment of the change in the concept of "special law." We may speak of special law when legal obligations apply differentially to different groups of people. According to Weber, special law originated in the differentiation of society into various status groups each with its traditional code and a degree of feudal independence from regulation by agents of the larger society. By contrast, the modern law of the centralized, bureaucratic state permits the different units of society to enter into legally binding contracts with each other. Thus, the power of the state is made to support bodies of special law created *de novo* by capitalists with interdependent interests.

Durkheim's theory of sanctions. Weber's theory converges with the ideas of the French sociologist Émile Durkheim (1893), who, following in a direct line of influence from Maine, was interested in the transition to a social order based upon contract.

Durkheim speculated that differences in legal structure so closely reflect underlying differences in social structure as to constitute indices of types of societies. In primitive societies the bonds of cohesion are formed by the global, undifferentiated norms of the "common conscience." In such a so-

ciety, law is repressive; it operates through sanctions designed to obliterate offenses to the common conscience and heal its wounds. Over time, as social solidarity comes to depend more and more upon the interdependence of specialized units, the legal order also becomes differentiated. Bodies of specialized norms develop, which are backed by *restitutive* sanctions designed to restore the balance of interests between competing but interdependent social groups. The new type of law permits private groups to negotiate within the context of general normative limitations and to contractually create for themselves viable systems of enforceable legal obligations.

Thus, Durkheim and Weber converged in a common recognition of an important dimension of structural variation in legal systems, namely, the extent of reliance on private action to create legal obligation. At the same time, both recognized the critical importance of the problem of the articulation of the authority of the larger society with private legal obligations.

Problems of structural analysis

Given Western legal values, one problem area stands out as the central concern of comparative structural analysis: What are the various ways that legal systems relate to their social environment and, in particular, what are the structural correlates of legal independence?

Defining the system. The first problem is to establish an analytical boundary between the legal system and its environment by defining the term "legal system." This is a notoriously difficult problem. Not the least of the difficulties stems from the fact that definitions that are adequate to the task of defining law in modern states fail to include the law of societies in which legal relations are inextricably entangled in other institutional contexts. One solution is to define the legal system functionally, so that its existence is not made to depend upon a structurally distinct set of roles or upon groups such as courts or police.

Many functional definitions rely upon the concept of social control (F. J. Davis et al. 1962, chapter 2). Law is defined as a type of social control that relies on a particular form of enforcement, usually enforcement through the legitimate use of force. Parsons (1962) and others would rather treat enforcement as a political function, external to the legal system. The advantage of this strategy is that it focuses attention on the variable structural arrangements through which legal systems come to have access to sources of coercive power.

In this view, the peculiar province of law is in-

terpretation. Social integration is often attributed to normative controls. However, social norms are not sufficiently specific to provide authoritative guides to conduct. Further, consensus about norms is often accompanied by dispute about the facts to which norms are to be applied. Accordingly, procedures develop for issuing authoritative versions of ambiguous situations of conflict and for propounding binding rules tailored to the particularities of these situations. Enforcement, on the other hand, is a political problem, a problem of mobilizing sufficient power to implement legal decisions.

Those who insist on including enforcement within the legal system can reply that interpretation is a necessary component of any act of enforcement. Interpretation could never be isolated in any single differentiated institution. A viable research strategy must guard against the fallacy of neglecting the fact that consequential interpretive decisions are continually being made at many points in the social structure.

System and environment. However the boundaries of the legal system are drawn, the problem of conceptualizing relations with the environment remains. There are a variety of ways of viewing this problem, but in Western thought one approach has dominated analysis. The problem has been defined as one of accounting for the independence of the legal system. Western political philosophy has accorded a high place to the "rule of law." From a sociological perspective, the rule of law refers to a society with a differentiated legal system, free from domination by any other institutional complex. Where the rule of law prevails, the legal process is subordinate only to established, known, and universalistic rules. Given this value concern, the task of comparative sociology is to account for the social basis of the rule of law.

To this end, we may distinguish four types of relations between the legal system and its social environment. First, the legal system may be *undifferentiated*, that is, it may have no differentiated structural home. Thus, legal functions are performed only as a by-product of activity within other institutions. For example, among the Eskimos socially enforceable interpretations are implicitly made in the context of public curing ceremonies and popular assemblies and in ritualized combat of various sorts, but there are no specialized procedures for formally proclaiming enforceable decisions (Hoebel 1954, chapter 5).

Second, a system may be *subordinate*. In this case specialized formal procedures, involving specially designated personnel, are present but legal

activities are controlled by other institutions. For example, justice may be dispensed by the king's ministers, as in ancient Egypt, or by priests subject to sacerdotal discipline, as in Sumer and Babylonia.

Third, a system may be *autonomous*. The legal practitioners may become so insulated from external controls as to become unresponsive to demands from other quarters. In these circumstances a legal system will develop according to an inner dynamic reflecting the dominant concerns of the practitioner group. Thus, for example, religious scholars may treat the law as a logical elaboration of theological concepts. The outstanding example of this is the development of the Semitic legal tradition.

The fourth category is the most complicated, as well as the most highly prized, in legal philosophy. Legal systems may be called *partially independent* when they are sufficiently insulated to permit independence in some spheres but not so protected as to prevent adaptive responses to the needs of other sectors of the society. The "ideal" form of partial independence is *procedural independence*. In this case, insulating mechanisms protect the day-to-day operation of the legal system and the interpretive process but do not make the system unresponsive to social interests, as formulated into general policies by legislatures and organized public opinion.

The concept of procedural independence must not be confused with the discredited idea that the judicial process can be purely mechanical or logical. American political science and legal realism have effectively shown that legal decisions necessarily involve choices between alternative policies. The difference between autonomy and procedural independence is that in the latter case adjudicators are responsive to policy premises originating outside the legal system.

Procedural independence is not only highly valued; it is also a crucially important case for sociological theory. Theorists as divergent as Weber (1922) and Engels (Marx & Engels 1848-1898, pp. 447-448 in 1949 edition) have stressed that procedural independence may contribute to the interests of particular social classes or institutions. An independent legal system, operating through the universalistic interpretation of established rules, is an efficient vehicle for legitimizing political domination. Further, such a system provides a set of stable expectations that facilitate economic calculation. A degree of procedural independence may emerge as a response to the conditions of stable economic relations, even in the face of considerable political domination of the legal process. For in-

stance, contractual arbitration in the Soviet Union became subject to the rule of law in order to foster accountability and stability in the relations between economic units (Berman 1950).

Law as social institution

The demand for stabilization of economic rights is only one of the forces supporting procedural independence. It is the task of comparative analysis to explicate the various structures and mechanisms that either insulate legal systems or make them vulnerable to external demands. Many protective devices are quite familiar: judicial tenure, judicial review, constitutional limitation, and judicial control over enforcement officials are obvious sources of judicial power. But from a sociological point of view the important question is, How are these mechanisms institutionalized? that is, How are they supported by concrete social arrangements?

A number of components of social structure are involved in the patterning of the relations between legal systems and other social institutions, but one factor has seemed especially important to sociologists. Comparative analysts have been particularly interested in the impact of the structure of professional specialization.

Legal specialists. The significance of the structural location and internal organization of professional groups is implicit in what has already been stated. Undifferentiated legal systems, having no specialized legal procedures, lack persons with special legal functions. Once a differentiated legal system develops, its character is profoundly affected by the social characteristics of its associated professionals. Indeed, one of the central propositions of comparative legal sociology is that autonomous and independent legal systems are supported by tightly organized professional groups, with an independent power base, whereas subordinate legal systems reflect the dependency and weakness of legal specialists.

Apart from this general proposition, it may also be asserted that specific characteristics of legal systems may be derived from attributes of professional groups. To take an obvious example, when adjudication is controlled by religious functionaries, then law is likely to have religious overtones.

Four major categories of legal specialists can be distinguished for present purposes. The first group may be broadly designated *adjudicators* and includes judges, magistrates, arbitrators, referees, hearing examiners, and similar functionaries. The second group consists of professional *advocates* of legal causes. The third group consists of legal *advisers*, such as the familiar English solicitor. No-

taries, conveyancers, and other draftsmen, also, belong in this category, and their significance should not be underestimated. As Weber ([1922] 1954, pp. 72–201, 210) has shown, where private elements are strong in the legal system, these “auxiliary” jurists assume special importance. When the state assures the bindingness of private agreements, the drafters of legal documents may become legal innovators who play an important role in shaping legal development.

The fourth group consists of the legal *scholars*—the teachers, writers, historians, and commentators whose contributions have been very important in both the Roman and civil law and in many non-Western traditions as well.

The four categories of legal specialists may or may not be differentiated from each other in practice, and the type and degree of internal differentiation is one of the important structural features of a legal system. Another of Weber's hypotheses is that the intensely practical and empirical character of the common law reflects the fact that it developed at a time when teaching was not differentiated from legal practice; there were no specialized scholars to impart an abstract ideological content to the law.

Professional organization. The internal differentiation of the legal profession is only one organizational element among many within the profession. Patterns of professional recruitment and advancement, the organization of professional training, and the organization and control of professional practice may have important consequences for the operation of the legal system. The explanatory potential of these variables is illustrated in Ulf Torgersen's study of the small and declining political role of the Norwegian Supreme Court (1963). The relative insignificance of judicial review is attributable to the patterns of recruitment to the court, which has been increasingly dominated by career bureaucrats rather than private attorneys.

Tight professional control over recruitment, training, advancement, and practice, founded upon a monopoly of access to technical legal knowledge and a monopoly of the right to legal advocacy, is one major source of independence and autonomy. However, there are other sources of legal power. The independence of legal specialists may be supported by the sponsorship of representatives of other powerful groups. Thus, adjudicators may be insulated from the domination of economic interests by the sponsorship of governmental power, or vice versa.

Symbolic factors are often especially powerful

in the legal sector. Legal specialists have rivaled religious functionaries in their capacity to assert successfully claims of special access to the sources of truth and right. Such claims have been supported by a variety of symbolic paraphernalia, ranging from magic and ritual to the more subtle trappings of modern judicial dignity. Ritualistic practices should not be discounted, but in modern liberal democracies the most important bulwark of legal independence has been the capture of the right to symbolically represent the limitation of governmental power. In this sense, the rule of law has supported itself; the independent professionals, who provide its social foundation, derive their influence in part from their symbolic embodiment of the normative regulation of power.

The legal process. Another approach to the articulation of the legal system and its social environment would eschew the abstract analysis of the structural location and internal organization of legal specialists in order to concentrate on the concrete transactions between legal specialists and representatives of other spheres.

These transactions include such processes as litigation, professional consultation, judicial enforcement, appointment or election to adjudicative office, and complaint to legal authorities.

According to this view, the proper strategy for comparative analysis is to study the structural arrangements that pattern interaction between legal specialists and others. The structural framework of legal transactions shapes their content and often provides leverage for either the legal system or its potential adversaries.

For example, one of the functions of formal legal procedure is to compel the parties to legal disputes to mold their concrete conflicts into issues subject to normative settlement. In so doing, the parties are forced to isolate normative issues and eliminate extraneous power factors. Power factors come to be defined as being outside of the scope of inquiry, and the adjudicator thus gains leverage on his clients.

On the other hand, the process of litigation is structured by the characteristics of cases that are preshaped by social organization before they come to the attention of legal authorities. Social structure generates a variety of types of conflict. Some conflict situations are channeled to the legal system; others are resolved in other contexts. Ready access to the legal system may depend upon a preferred position in the social order. Further, even among those who have ready access to the legal system, litigation is a strategic alternative to a variety of other modes of pressing interests. In consequence,

legal officials are not always in a position to control the types of issues that come before them or the structural context within which issues are presented. Thus, litigation can be conceived of as a series of transactions between the legal system and other social components, which are structured in part by the legal system and in part by external factors. Other transactions are subject to similar analysis.

Evolution of legal systems

A third approach to comparative analysis may be described as evolutionary: How, and in what sequence of steps, have differentiated legal systems emerged?

In this respect, Durkheim's thought runs counter to Weber. Weber was concerned with the emergence of the modern state from its feudal predecessors, and in this context he stressed the lack of centralized machinery of enforcement in many preindustrial societies. Durkheim, in his insistence on the importance of repressive sanctions in primitive society, seems to assume that the existence of societal enforcement mechanisms is not problematical. The anthropologists and historians who are students of legal evolution cannot agree with him. They continually search for the analogues to the legal process in "stateless" societies and trace the development of differentiated legal systems based upon a state monopoly of legitimate enforcement power.

The gradual development of central legal machinery in Europe has been known to legal historians for some time (F. J. Davis et al. 1962, chapter 2; Wigmore 1928). Scholarly interest in the evolution of legal procedure has been reawakened recently, in part because of concern for the problems of world legal order. The sequence of development from primitive self-help to central enforcement of norms through a universalistic, normatively regulated procedure has intrigued those who are interested in the possibility of a similar development at the world level [see INTERNATIONAL LAW].

R. D. Schwartz and J. C. Miller (1964), in a cross-cultural study of 51 societies, have shown that three structural attributes of legal procedure combine in a systematic pattern that can be described as a cumulative scale. The representation of interests by third parties is found only in societies with both special police forces and third-party mediation of disputes. Police and mediation sometimes occur in the absence of representation, and sometimes mediation is found in the absence of

any police to carry out the orders of mediating agencies. In some societies none of these procedural devices is present. The authors also found that the elaboration of legal procedure as measured by position on the cumulative scale is associated with measures of societal complexity, suggesting an evolutionary sequence of development. The sequence suggested is consistent with Western legal development as it has been pieced together by juristic scholars. The earliest legal systems are barely legal. The closest approximations to legal institutions are the rules governing kin-organized feuding and the sets of traditional compensations for wrongs. Later, regular procedures for submitting feuds to arbitration develop, but even then the parties may need to resort to self-help for enforcement. With the monopolization of legitimate force in the hands of the state, the legal system may rely on a specialized police force for enforcement of adjudicative orders. Finally, given a forum for binding and enforceable arbitration, the stage is set for the full development of professional advocacy.

Growth of legal pluralism. Historians have paid particular attention to the first two steps in the process. Law is said to appear in fully differentiated form once there is centralized enforcement of binding adjudication. From the perspective of comparative structural analysis the third step, also, is crucial, for with the appearance of institutionalized representation comes powerful support for procedural independence. For the first time there exists a set of legal specialists whose interests are not identical with the interests of mediators. It is possible that the new representer group will be captured by a particular set of interests, but theoretically the requisite social supports are present for the introduction of pluralism into the structure of the legal system. Professional representation can bring to the day-to-day administration of justice effective legal advocacy of the full range of interests present in society.

One step to pluralism is the creation of a market for professional services, so that legal representation can be purchased without regard to the content of the claims one wishes to advance. This requires either a high degree of professional neutrality or heterogeneity in the backgrounds and interests of recruits to professional service.

The establishment of a market for legal services is not a sufficient condition for pluralism, since the professional market will reflect the imperfections and inequalities of the economic structure of society. Since the inequalities of the marketplace

may be overcome by various procedural devices and by effective organization for legal advocacy, the variable organization of access to representation is one of the most important elements in the comparative study of modern legal systems.

Administrative law

In many instances ready access to the legal system has been promoted through the creation of administrative remedies, which permit rights to be secured by direct application to administrative agencies of government. Traditional courts and their sometimes cumbersome procedures are bypassed. At the same time, in their judicial activities the administrative agencies operate in at least a quasi-judicial fashion, preserving many of the forms of law and subjecting themselves to the rule of law. Administrative procedure tends to be more informal than traditional legal procedure, and is less likely to involve formal adversaries. It can therefore permit the adjudicator a relatively free hand to shape solutions that take into account the particularities of a given case. Yet, administrative procedure is normatively regulated, and the standards of impartiality and decision according to law apply.

The tremendous burgeoning of administrative law in the twentieth century is the most recent chapter in legal evolution. On this count, Durkheim's sense of evolutionary development fared well, for he successfully foretold the growth and elaboration of administrative law. For Durkheim administrative law was an integral part of the restitutive approach to law; the moral order, as represented by the common conscience, seemed to him less important than effective administration of a complicated network of obligations.

From this perspective, the growth of administrative law should be interpreted as consisting in the legalization of administration. It is simply an aspect of the process of bureaucratization that accompanies economic development. The increasing involvement of government in large-scale economic and welfare projects has been a worldwide phenomenon. The requirements of efficient administration and the interests of bureaucratic officials have combined to create pressure for the stabilization of rights and obligations.

Important as it is, the legalization of administration does not entirely account for the increasing domination of administrative law, for there has been a corresponding and converging development on the legal side. Many administrative tribunals have been created to operate in areas that have

been exclusively within the jurisdiction of courts. Numerous boards, commissions, and authorities have sprung up to deal with various criminal actions and tort claims.

Again one may invoke the argument of efficiency. The administrative tribunal has numerous practical advantages: it is less costly to litigants; it permits a high volume of litigation; it permits adjudication by specialists who are both technically skilled in particular areas and well acquainted with the concrete, practical problems of administration; it permits individualized treatment of complicated situations. But efficiency is not a sufficient explanation, unless one can show that particular groups have an interest in efficient administration. In this context, the growth of democracy is crucial (Evan 1962). Populist governments are responsive to demands for efficient administration of programs designed to produce public welfare and economic development. In the United States, for example, the growth of administrative law has been stimulated by a tendency for social welfare legislation to become bogged down in courts and by a movement to temper all legal administration by the application of a philosophy of social welfare.

Despite its humanitarian credentials, the growth of administrative law is often viewed with alarm in countries with a strong legal tradition. It is not surprising that administrative law should be surrounded by controversy, for its emergence is a classic case of a process that is usually associated with social strain. Whenever a group claims that special expertise or special familiarity with problems gives it a right to perform functions that were traditionally handled at other social locations, conflict ensues. Conflict is heightened when the technical specialist claims that his expertise frees him from some of the normative restraints that have governed performance of the function in the past. Yet this is exactly the claim of emergent administrative systems. The very differentiation of the legal function appears threatened as legal systems lose functions to substantively specialized but multifunctional enforcement agencies. All these processes have still to be adequately studied by students of contemporary social organization.

III

THE LEGAL PROFESSION

The legal profession encompasses all those who in view of their special competence in matters of law assume a distinctive responsibility in the administration of a legal order. The nature and extent of this responsibility may vary, and its locus may be found in one or in several social roles: judges, advocates, counselors, draftsmen, teachers, scholars. Because of special issues connected with it, the topic of the judiciary is treated more extensively under other headings [see JUDICIAL PROCESS].

The legal profession attracts the interest of both students of the professions and students of law and government. Political scientists, legal scholars, historians, and political sociologists are mainly concerned with the role of lawyers in politics and in the administration of justice. Recent sociological writings approach the bar from the perspective of the study of professions, focusing on such problems as professional independence, ethics, careers, recruitment, and relations with clients. The sociology of law draws on all these approaches.

The profession and the law

Whatever approach one takes to the study of the legal profession, it cannot be fully understood unless it is seen in the light of the special functions it performs for law and legal institutions. Indeed, the development and character of a legal profession are closely related to the growth and orientations of the legal order which it serves and within which it operates.

Where law is simply an expedient for the settlement of disputes or the accommodation of conflicting interests, the work of the lawyer involves little more than mastery of some techniques of social adjustment. The legal profession develops most fully when law is viewed as an embodiment of values. Society then requires specialized group energies for the protection of its legal heritage and may find them in that occupation whose interests are identified with the preservation of legal skills

and values. In this process, the legal craftsmen are transformed into a legal elite and assume the critical mission of maintaining the legal order and determining its subsequent development. Although values are at stake, a legal elite may not be necessarily called for when, as in ancient Greece or in imperial China, the values of law are not seen as distinct from the morality of the polity. In Athens the legal tasks of counsel and judge were performed by experienced citizens in the absence of any specialized legal profession. But the more the distinctiveness of law is emphasized and the more society aspires to legality, the greater is the need for an autonomous profession. The profession will require more or less independence and authority, depending upon the relative strength of community commitment to legal values.

While its role is partly fashioned in response to social needs, the legal profession carries much autonomous power over the orientations of the legal and social order. It may shape many features of a legal tradition. The growth of Roman law can thus be traced to the way in which *pontifices* and, later, praetors declared the law in private cases: by developing and extending formulas to be used as bases for actions at law, they created a system that allowed a continuing and highly pragmatic elaboration of legal ideas. The legal profession may also succeed in imprinting the value of law upon the community, as American arbitrators have done in the relations between labor and industry. It may even give a color of legality to moral norms and religious doctrines as did the rabbis in the Talmudic period and, in a different way, the canonists in the Roman Catholic church. Similarly, the inner weaknesses of the profession may breed corresponding weaknesses in the quality and authority of the legal order. This occurs when the profession becomes captured by the special interests it serves or when it so insulates itself as to weaken its participation in and responsibility for the solution of social problems. How competent the profession is to perform its role and what institutional means secure this capability are critical issues in the assessment of the legal profession.

Thus, the more developed a legal order, the more demands and responsibilities are placed upon its legal profession. The lawyer is called to bring a set of distinctive skills to his task. His special competence may be defined as an *expertise in the assessment of authoritativeness*; this follows from the special character of law as an authoritative order. Whatever kind of activity he may be involved in, the lawyer's distinctive contribution lies in his ability to formulate or criticize the *reasons* upon

which the authority of claims, decisions, policies, or actions rests. This ability is not confined to the evaluation of lawfulness; it includes a capacity to unravel issues, to scrutinize the rationale of policies, and to explore the firmness and test the relevance of evidence and inferences. The true lawyer is a generalist: he conveys this quality in his very posture of self-confidence and in the forthrightness of his style (Riesman 1954). To what extent such skills can be developed, of course, always remains problematic. This will vary partly with the richness of the resources a legal tradition makes available in its techniques of reasoning and criticism and partly with the capacity of the profession itself to instill this competence in some, if only a few, of its members. But some expertise of that nature is essential if the lawyer is to perform his task: that is, to add to social and legal institutions this strain toward the rational and the justified, which is the source of growth and strength of the legal order (Kadish 1961).

Typical legal roles. The legal profession is historically associated with the performance of some typical roles involving particular applications of this general expertise.

The *adjudicator* is responsible for making authoritative decisions on issues of right and responsibility in the light of legal principles. As the normative dimensions of adjudication rather than the mere settlement of disputes become more salient, there tends to be more pressure to reserve access to, and control of, this role to the legal profession.

The *advocate*, as a legal representative, carries out the task of pressing for the official recognition of claims of right. This role is closely tied to the adjudicative process, especially when the latter rests upon the adversary presentation of claims, as in the Anglo-American tradition. The significance of advocacy may however extend beyond the sphere of adjudication, especially when the law assumes a positive role in the fulfillment of human aspirations. The advocate may then acquire more direct functions in the formation of law; as a result new forms of advocacy will tend to develop in new institutional settings. The role of advocate is marked by conflict between the lawyer's responsibilities as an officer of the law and his commitment to the interests of his client. This is a source of strains not only for the lawyer, who may cope with them in a variety of ways, but also for the legal system as a whole. Different systems vary in the way they balance these conflicting duties, as well as in the degree to which they tolerate this ambivalence and allow for the free development of advocacy. Whereas partisanship has been a cornerstone of common-

law procedure, Soviet Russian law has until recently tended to restrict the right to counsel, and to insist on the advocate's primary loyalty to the courts and the public interest (Hazard 1960).

The *counselor* or *draftsman* has the special burden of assisting in the solution of social and human problems, while at the same time preserving the ideals of the legal order. The more emphasis that is placed on law as a creator of opportunities, the more this role is likely to develop. Thus, the notaries of northern Italy became pioneers in the fashioning of the law merchant, or commercial law, and the creation of negotiable instruments; their influence can be compared to that of modern lawyers in the growth of corporate enterprise. This development has been particularly significant in the United States, where business counseling became a primary focus of law practice to a much greater extent than in any European country.

The *jurist* or legal scholar is in charge of the systematic analysis and criticism of legal doctrine. One characteristic of law, as compared with other systems of norms, is that it contains its own built-in principles of criticism; the extension and refinement of these principles is a major task of the jurist. He may also share with the practitioners the role of training future lawyers. Jurists provide the profession with an instrument of self-scrutiny. The authority of their opinions varies, being generally higher in continental European than in Anglo-American law. One of the most important sources of law in imperial Rome lay in the *responsa prudentium*, that is, opinions in which famous scholars answered difficult questions of law. Under Hellenic influence, these jurists founded a tradition of formal legal analysis and teaching, which contributed to the progressive systematization and codification of Roman law; the Valentinian Law of Citations in A.D. 426 conferred legal authority on their writings. The revival and reception of Roman law in the Middle Ages was also the work of a school of jurists, the glossators of northern Italy, later followed by the scholastic postglossators in France and Italy. The German school of *usus modernus pandectarum* continued this tradition and, until the end of the nineteenth century, adapted the Roman doctrines to provide Germany with a workable common law; much of this work was incorporated in the German civil code of 1900.

Jurisprudence also attempts to clarify the ideals and perspectives of the legal order, a function that may be more effectively performed when jurists are not too closely bound to the practicing profession. There is, however, no clear evidence on this point, although the case of American law schools

may be suggestive. Because of weak ties to universities and a tendency to recruit teachers from the ranks of practitioners, American law schools have generally been oriented to the practical interests of the profession, with little concern for jurisprudence and broader issues pertaining to the quality and needs of the legal order.

Lawyers have also been called to assume many other roles, such as mediators, managers in private business, politicians, and public administrators. How extensively they participate in such roles, especially in government, may both affect and reflect the authority of the law. Of special importance is the character of their participation. Their only contribution may lie in the ability to accommodate interests and manipulate social structures, a kind of activity in which they would not significantly differ from any trained politician (Eulau & Sprague 1964). Or they may bring to public life some of their own distinctive commitments and competence and help evolve, in both private and public government, an orientation to orderly procedure and the ideals of legality.

Structure of the profession

To analyze the structure of the legal profession is to ask how the social organization of the profession affects the role it performs in the legal order. The focus here is on internal and external sources of weakness or strength.

Legal education. By controlling access to the profession and the training of future lawyers, legal education has an important bearing on the character of the profession and the orientations of the law. Whether the law becomes the property of a privileged class or of the whole polity depends to some extent upon criteria of access to the profession. When admission is limited to a narrow segment of society, the services of the profession may be oriented primarily to this clan. The more the legal career is viewed as an avenue to political power and social status, the more efforts will be made to keep access open, especially where there is strong antipathy toward the establishment of governmental elites. This has been evident in the United States (Hurst 1950). Although wide accessibility may make the law responsive to a larger range of interests, it may also create problems for the profession in its endeavor to preserve standards of quality. American attempts to raise educational standards of admission to the bar have met only limited success: the shift from apprenticeship to academic training has been accompanied by the development of a highly stratified system of education, with only relatively few high-standard

university law schools at the top. The bottom consists of a large number of low quality, part-time schools that have weak or no university ties and seek merely to prepare the student for the bar examination.

Methods of legal training affect the skills and perspectives lawyers bring to their practice and thereby shape many features of the law. Max Weber has noted the relation between apprenticeship and the pragmatic responsiveness of the common law, as contrasted with the more intellectual and formalistic treatment of the law arising from university education in Europe (1922). Orientations to law are thus created, which confer on the legal order more or less rigidity or flexibility. Some can better preserve the "open texture" of the law, allowing law to incorporate social change while retaining its continuity; the Anglo-American system has been remarkable in this respect. Other orientations are apt to freeze the structure of legal rules and to paralyze processes of legal change; the academism of legal education in Europe—a tradition that dates back to the glossators—tends to promote this rigidity. Social reforms are then more likely to be sought by means outside the law, thus arousing critical problems for the stability of both the legal and the political order. This tendency can be observed in some civil-law countries, especially in South America.

In a more direct way, legal education may become a source of law. In the very act of ordering legal materials for pedagogical purposes, law is divided into branches, and these are organized around governing concepts. The institutes of Roman law were originally purely pedagogical instruments; however, by systematizing the principles of Roman law, they started a movement toward codification and became an authoritative source of the *Corpus juris civilis*. In the process of being taught, law is thus given a structure which reflects the changing emphases of positive law and the needs of the practitioners. But this structure also provides ideas and perspectives which may affect the capacity of the law to cope with social change. Thus, the disappearance of the law of persons as a separate branch of legal study tends to impoverish the resources of American law for recognizing new forms of status.

Even more significant for the legal order is the role of legal education in providing lawyers with distinctive modes of analysis and reasoning. The case method, as practiced in American law schools, may be peculiarly competent to impart these skills. It may also tend, however, to create a perspective in which law appears as an outcome of controver-

sies rather than a way of implementing values. More importantly, by identifying the main locus of law in appellate decisions, it may promote a restricted conception of the legal. Attention is diverted from the variety of ways and settings in which law can emerge and be administered. Even in its empirical focus on decisions, the case method overstates the role of the judiciary, neglecting legislation and administrative decision making. It may thus limit the capacities of legal education to prepare lawyers for a period such as the present, when the role of law is being extended beyond its traditional confines.

Professional autonomy. The integrity of the law depends in part upon its ability to respond to political demands while maintaining its commitment to reason and impartiality. A continuing problem for the practicing lawyer is to remain sensitive to social needs and interests without becoming their captive and to preserve his autonomy without withdrawing himself from practical concerns.

Captivity may, of course, take a crude form, as when a political regime seizes control over the profession in order to neutralize a potential source of criticism (Kirchheimer 1961). It can, however, develop in more subtle forms where the profession is otherwise left free to serve. The lawyer can become the captive of his clients' interests: an insecure practice, for example, makes it harder for him to resist pressures from clients for fear of losing them to competitors. This condition arises when the demand for legal services remains weak and intermittent, as it is among the lower classes, or when there is intense competition from other lawyers or from such groups as realtors and accountants, who encroach upon areas of practice requiring only low level and standardized skills (Carlin 1962). Captivity can also result from too intimate involvement in the affairs of particular clients. Lawyers may thus tie themselves to a small number of institutional clients who demand extensive and continuing services, or as "house counsel" (members of a legal department) they may become too closely identified with or too submissive toward the enterprise or agency which employs them.

Professional integrity may also be undermined in the lawyer's dealings with courts and government agencies. The lower the standards of these institutions or the more open they are to outside political influences, as lower courts often are, the more they create opportunities and pressures which may attenuate norms of professional conduct. Continual practice before an agency may also

lead the lawyer to share the perspectives of its administrators.

A common consequence of captivity is to deprive the lawyer of his special identity: he is transformed into a manipulator of social and economic structures who is no longer committed to the use of distinctively legal methods or resources. In this process, he tends to become indistinguishable from the politician or the business operator. Law is then made to appear as simply an expedient for the promotion of special interests, and the distinction between law and politics is lost.

The lawyer can resist pressures by avoiding involvement or insecurity, but such avoidance entails its own difficulties. A too rigid insistence upon independence and distinctiveness may divorce the lawyer from his clients' problems and needs, thus weakening the contribution law might make to their solution. The lawyer may then find himself confined to the passive role of providing technical help in the event of legal trouble. Under such conditions, law tends to evolve into legalism. A special view of law is conveyed which stresses the formalism of the legal order and the obstacles it creates to effective problem solving. Law may thus be emptied of its moral and political significance and reduced to its purely technical and positivistic aspects. Paradoxically, in seeking to protect his autonomy the lawyer may so insulate himself as to weaken both his own authority and the authority of the law, perhaps eventually becoming a docile servant of corporate or political power. The history of the legal profession in Nazi Germany illustrates this process.

Organization of the bar. The profession has evolved a number of structural arrangements which can be more or less successful in securing a viable autonomy. Apart from its effectiveness in this regard, the social organization of the bar may also influence patterns of development in the law.

One organizational device is to create within the profession an elite specially charged with the protection of legal ideals. While this segment insulates itself from outside pressures, others in the profession are left free to respond to and accommodate the variety of demands that are made on the legal order. The British system has achieved this differentiation by developing a small and specialized class of barristers, who enjoy a monopoly of practice in the higher courts and deal with clients only through solicitors. The latter do most of the client counseling and take care of cases in the lower courts and government agencies (Jackson 1940). In the United States, the large law firms have developed a very high level of tech-

nical proficiency in legal work, have restricted their practice to the most stable and secure clientele, and have limited their contacts to the top levels of government and the judiciary (Smigel 1964). Special training institutions, such as the Inns of Court in Britain and the American Ivy League law schools, help to strengthen these elites, while sharing in their trusteeship for the legal order.

The services of the elite bar tend to benefit those most competent to pursue their interests through use of the legal process. Thus, a critical issue is whether the elite can preserve its loyalty to legal institutions and its responsibility for the law as a whole, for it runs the risk of becoming so identified with the aims of a special clientele as to restrict its concerns to those areas of the law that best serve these aims. This encourages a highly selective development of the law and impairs recognition of legal demands arising from other segments of society. Large American law firms have thus been strongly criticized for their too exclusive services to corporate interests and their loss of concern for general legal values (Berle 1933). Moreover, in the United States the large metropolitan bar is highly stratified, with little mobility or communication between the upper and lower strata (Carlin 1966). The more the elite is cut off from the lower levels of the profession and of government, the more difficult it becomes to incorporate in the legal order the demands that are brought to these levels.

Formal associations. The weaker the sense of common purpose is within the bar and the more threatening the conditions under which it operates, the more pressing is the need for instruments of self-scrutiny and control. The practicing profession has traditionally been organized into guildlike associations, such as the Inns of Court in Britain and the *Ordre des Avocats* in France, which have often been quite powerful in regulating the practice of law. In the United States, the organization of the bar used to consist exclusively of small local and voluntary associations with little cohesion and authority. It still remains today highly fragmented, and primarily concerned, even in the exercise of disciplinary control, with the protection of the profession against public intervention and lay encroachments. A movement of reform, starting in the 1870s, led to the establishment of state bar associations and later to the integration of some of these. In states which have an "integrated bar," membership is compulsory for all practitioners in the state, and the association can thus enjoy greater security and larger resources. The American Bar Association

was created in 1878 and progressively developed into a federation of state and local groups. It has assumed a prominent role in the bar as a whole, elaborating standards of admission and canons of ethics and recommending reforms in the law and the administration of justice. In legal reform it collaborates with two specialized organizations of the profession, the American Judicature Society and the American Law Institute. The latter undertook to codify American common law in a "Restatement of the Law." This work is still in progress. Contributions of the Institute include the drafting of model acts and codes in various branches of the law.

Types of practice. The practice of law may take a variety of forms, some of which have already been mentioned. Lawyers may work on their own or associate in firms of various size. They may serve mainly discrete individuals or organizations and businesses; the role of family lawyers, such as attorneys in the field of probate and estate, tends to decline as the family loses its economic functions.

Not all areas of legal practice allow the same quality of work. For instance, workmen's compensation and, frequently, personal injury call mainly for mass production and standardized legal techniques. In other fields, such as criminal law and domestic relations, "marriage counseling" and political manipulation are often more salient than legal craftsmanship (O'Gorman 1963). The lawyer is then likely to feel frustrated and threatened in his professional identity. The character of the market for services may also affect professional integrity: lawyers can more easily preserve their dignity when they can count on a secure and regular clientele. Others, however, especially those with low-status clients, have to keep continually searching for business, establishing connections, and resorting to such expedients as "ambulance chasing," through which potential clients are located and advantage is taken of whatever claims and speculations can be aroused. In this very process they become deprofessionalized (Carlin 1962).

A new type of practice has begun to develop as organized groups, such as labor unions and trade associations, assume the function of providing to their members the services of their retained counsel. The special contribution of these groups lies in their ability to aggregate common interests and to articulate legal demands. Resources can then be mobilized to press these claims in a systematic way and thereby promote legal change.

The practice of law has become more specialized: lawyers specialize according to the class of

clients they serve, the agencies with which they deal, or the branch of the law they handle. In the United States, this trend has been facilitated by the expansion of law firms (Smigel 1964). Specialization is particularly significant for the growth of legal doctrine in undeveloped areas of the law and where special government institutions must be made accountable and sensitive to social demands. Specialized lawyers have thus played an important role in the development of administrative law and labor law and in the extension of constitutional rights in the United States.

The explosion of advocacy

Modern social transformations tend to place new demands on the legal order and the legal profession. Government—public and private—is asked to perform tasks and satisfy needs that were formerly taken care of in more informal settings. Thus, in contrast to a rather passive role in the past, law and legal institutions are being summoned to participate more positively in the task of fulfilling human aspirations and accomplishing social purposes.

The effectiveness of law in this new role depends upon considerable expansion of social resources for legal criticism. Modern times may thus witness what has been termed an "explosion of advocacy," with corresponding demands for critical changes in the services of the legal profession. The lawyer is called upon to relinquish his passive stance and assume an active role in the transformation of privileges into rights and in the development of rationality and competence in government institutions (Cahn & Cahn 1964).

This enlarged responsibility will require greater initiative on the part of the profession in scrutinizing the variety of social settings where decisions are made affecting established or incipient rights. The traditional role of law schools and professional associations will need re-evaluation in this respect. More positive responsibilities may fall upon legal departments, in view of their growing role in public and private organizations. Special agencies, similar to the Scandinavian office of ombudsman, may also be designed to carry out this task of legal criticism.

Wherever government relies upon self-help for the assertion of claims and interests, the viability of the system will ultimately depend upon the legal competence of the citizenry, that is, its capacity to make effective use of the legal machinery. To promote this competence is one of the major tasks of the legal profession. One requirement is that the provision of legal services be extended.

Pressures on the profession to broaden its availability have been heightened by social demands for equality and political enfranchisement. It is unlikely, however, that the enlarged need for legal services can be fully met with existing institutions, such as legal aid and public defender offices. Serious limitations of available organized services can be seen in their dependence upon traditionally restricted sources of support, their routine treatment of cases, and their view of legal assistance as a form of public welfare ("The Availability of Counsel . . ." 1965).

As legal institutions become increasingly used and crowded, a new burden falls on the lawyer. The working of both law offices and tribunals comes to depend upon establishing standardized methods for the mass processing of cases. Thus the operation of rules and procedures tends to become a routine which escapes criticism and blocks adaptation to unusual cases and new experiences. Special efforts are then required of the lawyer in continually subjecting procedures to re-evaluation and in opening them to challenge and change.

However, more than a simple extension of legal services may be needed. The traditional model of individual representation and counseling may prove inadequate to the task of developing legal competence. New types of legal services must be evolved. Thus, the older emphasis on serving individual clients may have to be supplemented and in part replaced by *organizational advocacy*: here legal services are provided to an organization representing the common interests of a group or they are made available to members of the group through intervention by the organization. This transformation has already taken place in American industry, where organized labor has secured the services of specialized labor lawyers to support the legal interests of its constituents. Group services will have to expand if legal assistance is to be made effectively available ("The Availability of Counsel . . ." 1965). Experience has shown that persons who are insecure and lack social support for the assertion of their claims need a representative organization to lend them its strength and resources. Neighborhood law firms and defense organizations such as the National Association for the Advancement of Colored People and the American Civil Liberties Union constitute a step in this direction. As these changes proceed, new specializations will develop within the legal profession, thus promoting the growth of new, still inchoate, fields of law.

Together with the growth of group representa-

tion, there is a drift away from the passive acceptance of individual cases as they come. This traditional approach is consistent with an adversary system in which the presentation of legal issues depends upon the development of specific controversies between defined interests. This system tends to divert attention from structural sources of injustice. As individual demands become organized, *strategic advocacy* develops: the lawyer can select and possibly generate issues for the purpose of challenging practices and pressing recognition of new rights (Cahn & Cahn 1964). In this process, adjudication becomes less dependent upon disputes and can address itself more directly to issues of policy and the broader interests at stake. Adversariness is then used as a way of clarifying policy problems; at the same time, the role of the *amicus curiae* develops, and there is greater reliance upon forms of declaratory relief, where questions of law are clarified without the necessity of deciding on the outcome of a particular dispute. More importantly, the growth of the law tends to be less contingent upon the more or less random occurrence of cases and to proceed along lines of more systematic planning.

IV

LAW AND LEGAL INSTITUTIONS

More scholarship has probably gone into defining and explaining the concept of "law" than into any other concept still in central use in the social sciences. Efforts to delimit the subject matter of law—like efforts to define it—usually fall into one of several traps that are more easily seen than avoided. The most naive beg the question and use "law" in what they believe to be its common-sense, dictionary definition—apparently without looking into a dictionary to discover that the word "law" has six entries in Webster's second edition, of which the first alone has 13 separate meanings, followed by five columns of the word used in combinations. German and French have even more complex ambiguities, since their comparable words (*Recht*, *droit*) include some dimensions for which English uses other words.

Sophisticated scholars, on the other hand, have been driven either to write treatises on the art and pitfalls of definition (Cohen & Hart 1955) or, like Stone (1964), to realize that in relation to a noetic unity like law, which is not represented by any-

thing except man's ideas about it, definition can mean no more than giving the reader a set of mnemonics to remind him what has been talked about. It was Kant who said, "The lawyers are still seeking a definition of their concept of law." A century and a half later Stone stated that "law" is necessarily an abstract term, and the definer is free to choose a level of abstraction; but by the same token, in these as in other choices, the choice must be such as to make sense and be significant in terms of the experience and present interest of those who are addressed" (1964, p. 177).

Definitions of "law"

Even if we agree with Hart (1954) that the searches for definition and the concomitant search for security that they represent became serious only in the time of Austin (and Kant's remark would seem to belie this), it is apparent that schools of jurisprudence have risen, battled, and fallen on bastions erected on one meaning or another. Austin has permanently affected British jurisprudence by emphasizing the command aspect of a law and pointing out that the law is a command of the "sovereign" (itself an ambiguous concept). Since then lawyers have for generations and without signal success been arguing whether Austin's stipulations applied only to developed systems of "municipal" law and whether he himself really gave the point of command such primacy.

The American "realists" clustered around Oliver Wendell Holmes's dictum that law is a prediction of what a court will enforce. Continental scholars tended to be more concerned with the moralistic "right" and "ought" aspects of the rules of law and have gone deeply into moral philosophy.

In the effort to define "law," some modern scholars like Hart (1954) conclude that there are three "basic issues": (1) How is law related to the maintenance of social order? (2) What is the relation between legal obligation and moral obligation? (3) What are rules and to what extent is law an affair of rules? Others (Stone 1966) describe several sets of attributes that are usually found associated with law. Accordingly, law is (1) a complex whole, (2) which always includes social norms that regulate human behavior. These norms are (3) social in character, and they form (4) a complex whole that is "orderly." The order is (5) characteristically coercive and (6) institutionalized. Law has (7) a degree of effectiveness sufficient to maintain itself. Anthropological studies of law in the non-Western world have followed a similar course. To cite one of the most vivid and orderly presentations, Pospisil (1958) examined

several attributes of the law—the attribute of authority, that of intention of universal application, that of *obligatio* (the right-obligation cluster), and that of sanction. In his view, the “legal” comprises a field in which custom, political decision, and the various attributes overlap, though each may be found extended outside that overlapping field, and there is no firm line, but rather a “zone of transition,” between that which is unquestionably legal and that which is not.

It was Kantorowicz (1958) who pointed out that there are many subjects, including some of a nonlegal nature, that employ a concept of law. He perceived that each needs a different definition of “law” if it is to achieve its purposes. He then proceeded to a more questionable point: it is for “general jurisprudence” to provide a background to make these differing definitions sensible—in short, it is the task of jurisprudence to elicit meaning from this cacophony of attempted definitions. Kantorowicz’s method in jurisprudence is very like Pospisil’s in anthropology. Instead of trying to find points for definition of law, Kantorowicz examined some characteristics of law that are vital to one or more of the specific definitions. Law is thus characterized by having a body of rules that prescribe external conduct (it makes little immediate difference to the law how one feels about it—the law deals in deeds). These rules must be stated in such a way that the courts or other adjudging bodies can deal with them. Each of the rules contains a moralizing or “ought” element—and Kantorowicz fully recognized that this “ought” element is culturally determined and may change from society to society and from era to era. Normative rules of this sort must, obviously, also be distinguished from the real uniformities by which men (sometimes with and sometimes without the help of courts and lawyers) govern their daily round of activity. Law is one of the devices by means of which men can reconcile their actual activities and behavior with the ideal principles that they have come to accept, and can do it in a way that is not too painful or revolting to their sensibilities and in a way which allows ordered (which is to say predictable) social life to continue. No act is wholly bad if it is “within the law”; no law is wholly good if it condones “immoral” action.

Rules. Custom is a body of more or less overt rules which express “ought” aspects of relationships between human beings and which are actually followed in practice much of the time. Law has an additional characteristic: it must be what Kantorowicz calls “justiciable,” by which he means

that the rules must be capable of reinterpretation, and be actually reinterpreted, by one of the legal institutions of society so that the conflicts within nonlegal institutions can be adjusted by an outside “authority.”

It is widely realized that many peoples of the world can state more or less precise “rules” which are, in fact, the ideals in accordance with which they think they ought to judge their conduct. In all societies there are allowable lapses from rules, and in most there are more or less precise rules (sometimes legal ones) for breaking rules.

Legal institutions. In order to make the distinction between law and other rules. It has been necessary to introduce furtively the word “institution.” We must now make an honest term of it. A social institution can be defined as a group of people who are united (and hence organized) for some purpose; who have the material and technical means of achieving that purpose or at least of making rational attempts at it; who support a value system, ethics, and beliefs validating that purpose; and who repeat more or less predictable activities and events in the carrying out of the purpose (Malinowski 1945). With this rubric, all human activity can be viewed either as institutionalized or as random (and the degree of random behavior may be the most diagnostic feature of any society). It need hardly be added that “institutionalized” does not necessarily mean “approved” by the people who participate in the institutions.

With these ideas it is possible to distinguish legal institutions from nonlegal ones. A legal institution is one by means of which the people of a society settle disputes that arise between one another and counteract any gross and flagrant abuses of the rules of the other institutions of society. Every ongoing society has legal institutions in this sense, as well as a wide variety of nonlegal institutions.

It can be pointed out that some nonlegal institutions—the priestly, the psychiatric, and the like—serve the function of settling disputes. To make the distinction between legal and nonlegal, social scientists generally invoke the doctrine of coercion and use of force. Such a settlement is sensible because the legal institutions with which modern Western lawyers deal are usually associated with a political unit of which the state is one type. A political organization *ipso facto* supplies theorists with a “sovereign” of Austinian type and the “enforcement” predicated by Holmes and others. From this point of view, then, legal institutions must have two defining criteria: (1) they must settle the

disputes that arise in other (nonlegal) institutions, and (2) they must be associated with (or even constitute) some sort of political organization. Obviously, for some purposes—particularly in the study of less-developed legal systems—the second criterion can and must be dropped; for most purposes of Western jurisprudence, just as obviously, it is probably necessary to retain it.

In carrying out the task of settling difficulties in the nonlegal institutions, legal institutions must have specific ways to (1) disengage the difficulties from the institutions of origin which they now threaten, (2) handle the difficulties within the framework of the legal institution, and (3) set the new solutions back within the processes of the nonlegal institutions from which they emerged. Indeed, the presence of such characteristics is a vivid index of the presence of a political organization.

There are, thus, at least two aspects of legal institutions that are not shared with other institutions of society. First, legal institutions alone must have some regularized way to interfere in the malfunctioning (and, perhaps, the functioning as well) of the nonlegal institutions in order to disengage the trouble case. Second, there must be two kinds of rules in the legal institutions—those which govern the activities of the legal institution itself (called “adjectival law” by Austin and “procedure” by most modern lawyers) and those which are substitutes for, or modifications or restatements of, the rules of the nonlegal institution that has been invaded (called “substantive law”). The above are only the minimal aspects that are shared by all known legal institutions.

Seen in this light, the distinction between law and custom is fairly simple. Customs are rules (more or less strict and with greater or less support of moral, ethical, or even physical coercion) about the ways in which people must behave if social institutions are to perform their tasks and society is to endure. All institutions (including legal institutions) develop customs. Some customs in some societies are reinstitutionalized at another level: they are restated for the more precise purposes of legal institutions. When this happens, therefore, law may be regarded as a custom that has been restated in order to make it amenable to the activities of the legal institutions. In this sense one of the most characteristic attributes of legal institutions is that some of these “laws” are about the legal institutions themselves, although most are about the other institutions of society, such as the familial, economic, political, and ritual.

Malinowski, by his little book *Crime and Custom*

in *Savage Society* (1926), has widely influenced lawyers with a faulty mode of distinguishing law from nonlaw. His idea was a good one; he claimed that law is “a body of binding obligations regarded as right by one party and acknowledged as the duty by the other, kept in force by the specific mechanism of reciprocity and publicity inherent in the structure of . . . society.” His error was in equating what he had defined with the law. It is not law that is “kept in force by . . . reciprocity and publicity” ([1926] 1961, p. 58). It is custom as we have defined it here. Law is better thought of as “a body of binding obligations regarded as right by one party and acknowledged as the duty by the other” which has been reinstitutionalized within the legal institution so that society can continue to function in an orderly manner on the basis of rules so maintained. In short, reciprocity is the basis of custom; but the law rests on the basis of this double institutionalization.

Rights. One of the best ways to perceive the doubly institutionalized norms, or “laws,” is to examine the smaller components as they attach to persons (either human individuals or corporate groups) and so to work in terms of “rights” and their reciprocal “obligations.” In the framework of rights and duties, the relationships between law and custom, law and morals, law and anything else can be seen in a new light. Whether in the realm of kinship or contract, citizenship or property rights, the relationships between people can be reduced to a series of prescriptions with the obligations and the correlative rights which emanate from these prescriptions. In fact, thinking in terms of rights and obligations of persons (or role players) is a convenient and fruitful way of investigating much of the custom of many institutions. Legal rights are only those rights which attach to norms that have been doubly institutionalized; they provide a means for seeing the legal institutions from the standpoint of the persons engaged in them.

The phenomenon of double institutionalization of norms and therefore of legal rights has been recognized for a long time, but analysis of it has been only partially successful. Legal rights have their material origins in the customs of nonlegal institutions but must be overtly restated for the specific purpose of enabling the legal institutions to perform their tasks.

Sanctions. Many scholars, in comparative studies, have focused attention on the sanction for purposes of determining what is to be included in the “legal” field. Use of the term “sanction” has the advantage of allowing the scholar to beg the

question of the Austinian sovereign. Sanction is generally understood to mean what the law itself says will or may happen to one found guilty of having transgressed a legal rule. The word is often used in common parlance to mean "the teeth in the law." When it is used as a verb, its true ambivalence becomes apparent. "To sanction" something is in ordinary usage not to interfere with someone's doing it; yet jurists also use it to mean "visit an evil on doing it," and social scientists have extended the word "sanction" far beyond its technical meaning for modern law. Radcliffe-Brown (1934a) described positive and negative sanctions for behavior, embracing not only penalization of non-conformity but also rewarding of conformity—and all this without specifying precisely who confers rewards or inflicts punishments.

The problem of sanction would seem to be better summarized in terms of legal institutions which, in some situations, apply specific types of correction to adjudged breaches of law. That is, the "sanction" is the body of rules according to which legal institutions interpose themselves for the purpose of maintenance of a social system so that living in it can be comfortable and predictable.

Law and social science

It is apparent that we must examine two further factors. First, what sort of definitions of law may be needed by the social sciences? Second, and related to this, how can social scientists go about investigating the legal institutions and the legalization of rights in any specific culture or in any concatenation of cultures?

The kernel of the social scientist's concept of law must be found, I believe, in the phenomenon of double institutionalization of rights: once within customary institutions, then again within the legal institutions. Therefore he is required absolutely to study both the legal institutions and the social institutions on which they feed—and only in this way can he ever make any progress with the thorny problem of the relationship between law and society.

The social scientist studying law is quite right when he considers the law a type of social superstructure to be judged by criteria or values of the social sciences. He is, however, quite wrong if he extends this position to mean that he need not consider what is known about the law on its own ground. The determining variables of the law may be considered as part of a social field; but equally so, the social field must be considered by jurisprudence. In short, what is required is a sort of stereoscopic vision, looking at data with the lens of

jurisprudence in one eye and the lens of social science in the other.

Seen thus stereoscopically, a legal right (and, with it, a law) is the restatement, for the purpose of maintaining peaceful and just operation of the institutions of society, of some but never all of the recognized claims of persons within those institutions; the restatement must be made in such a way that these claims can be more or less assured by the total community or its representatives. Only by so viewing legal rights can the moral, religious, political, and economic implications of law be fully explored.

In fact, a primary problem of all legal studies may be the intersecting of the law and the other institutions of society. This relationship is no mere reflection of society in the law: it must be realized, rather, that the law is always out of phase with society, specifically because of the duality of the statement and restatement of rights. Indeed, the more highly developed the legal institutions, the greater the lack of phase, which not only results from the constant reorientation of the primary institutions but is magnified by the very dynamics of the legal institutions themselves (Stone 1964, chapter 1, sec. 1).

Thus, it is the very nature of law and its capacity to "do something about" the primary social institutions that create the lack of phase. Moreover, even if one could assume perfect legal institutionalization, change within the primary institutions would soon jar the system out of phase again. What is less obvious is that if there were ever to be perfect phase between law and society, then society could never repair itself, grow and change, flourish or wane. It is the fertile dilemma of law that it must always be out of step with society but that people must always (because they work better with fewer contradictions, if for no other reason) attempt to reduce the lack of phase. Custom must either grow to fit the law or it must actively reject it; law must either grow to fit the custom or it must ignore or suppress it. It is in these interstices that social growth and social decay take place.

Social catastrophe and social indignation and resultant changes in custom are sources of much new law. With technical and moral change new situations appear that must be "legalized." This truth has particular and somewhat different applications to developed and to less highly developed legal systems. In developed municipal systems of law, in which means for institutionalizing behavior on a legal level are already traditionally concentrated in political decision-making groups such as legislatures, there is a tendency for the legal institution

not to reflect custom so much as to shape it. As developed nations put more faith in their legislatures, nonlegal social institutions sometimes take a very long time to catch up with the law. On the other hand, in less-developed legal systems, it may be that little or no popular demand is made on the legal institutions, and therefore little real contact exists or can be made to exist between them and the primary institutions (Stone 1966, chapter 2, sec. 17). Law can become one of the major sources of innovation in society.

The social scientist's first task, then, is the analysis of the legal institutions to be found and their interrelationships with the nonlegal institutions of society. There may be courts as in some parts of indigenous Africa or indigenous Europe; there may be self-help, oracles, moots, town meetings, contests, and certain types of feuds (although most feuds do not correct the difficulty and feed the corrected situation back into the nonlegal institutions of society). The social scientist can examine the particular types of customs that are legalized in any particular society. He can begin the process of comparing the customs of mating and child rearing with the laws of marriage; the customs of trading with the laws of contract; the customs of interpersonal relations with the law of tort; the customs of approved behavior with criminal law.

And what will he find? He will find that the practice of law is a force by itself, a force for preserving and molding society that both has its roots irrevocably in social institutions and must supersede any particular historicoethnographic phase of them.

The social scientist's next task is the reporting and comparison of legal institutions in the terms of the people who participate in those institutions and the subsequent comparison of those terms with the terms in which other people live in analogous or similar institutions.

His third task is the exposition of what Hoebel (1954) has called the "postulates" of that people's law: the assumptions held about the "natural" ways of the world, most often without even a possibility of overt statement, by the people who live by a custom and a law. These postulates lie behind the law as they lie behind every other aspect of that people's activity. They are those "values," or unquestioned premises, on which a people bases not merely its behavior (including law) but its moral evaluation of behavior (including ethics). The postulates behind a legal system are congruent with the postulates behind the accompanying economic or religious system. What may seem blatant discrepancies and contradictions and, indeed, hy-

pocrisies (as between Sunday school and the market place) are in fact no more than inadequate analyses of the postulates. A postulate lying behind Anglo-American law is that the human body is inviolably private unless marriage or certain contracts have been entered into; a postulate behind Eskimo law is that life is hard and that kinship, amity, or love between individuals cannot be allowed to override the welfare of the society. The postulates underlying a people's law also underlie the rest of its culture. Law cases provide one of the best mechanisms by which the ethnographer can capture these postulates and make them overt.

LAW, JOHN

John Law of Lauriston (1671-1729), economist, banker, merchant, and statesman, founded the first Bank of France and is generally held responsible for the Mississippi Bubble. He was born in Edinburgh, the son of a prosperous goldsmith-banker, who died when Law was only 13. However, his mother, who was distantly related to the duke of Argyll, saw to it that Law studied both theoretical and applied economics. Law was a handsome man with an engaging personality and the ability to make a favorable impression on important people. Nevertheless, he spent many years as a fugitive from British justice, having been sentenced to death in 1694 for killing a man in a duel. It was not until 1717 that he was pardoned by George I, and his extensive travels during his exile enabled him to study diverse economic institutions and conditions abroad.

Law's early interest in money and banking may well have been intensified by the adoption of William Paterson's plan for the Bank of England in 1694, since Paterson was a fellow Scot. Over the next 20 years Law was to spend much time and energy making proposals for the establishment of banks, both in Scotland and on the Continent, and these efforts eventually culminated in the founding of the first Bank of France.

The original proposal was outlined in two drafts for a privately owned Bank of France, which he sent in 1702 to Madame de Maintenon, the morganatic wife of Louis XIV. In a brief theoretical introduction, Law enumerated as components of the money supply: Bank of England stock, stock in the English and Dutch East India companies, exchequer notes, and Dutch government bonds—a concept of money supply that was destined to lead to his most calamitous mistakes in monetary policy. Each province of France would have a branch of the Bank, with a fixed allotment of capital, and notes payable to bearer would be redeemed at the parent Bank in Paris or at any one of the branches. Law argued that the Bank of France, like the Bank of Amsterdam and the Bank of England, would increase the money supply, lower the rate of interest (thereby raising the price of land and stimulating economic activity), reduce losses from fire and theft, eliminate shipments of specie from the provinces to Paris, and, through its notes, provide a safe and convenient medium of exchange for travelers. Law's project was not accepted: the French finance minister, Michel Chamillart, was also war minister and was preoccupied with military problems, and Madame de Maintenon's prejudice against Protestants and foreigners did not predispose her to support Law.

But Law did not have to wait long for another opportunity to propose a banking scheme. He was in Edinburgh in the summer of 1704, when Scotland was suffering a depression subsequent to the failure of William Paterson's Darien expedition. The suspension of specie payments by the Bank of Scotland in December 1704 intensified the crisis, and this stimulated Law to propose to the Parliament of Scotland in 1705 that a land bank be created. The proposal was published anonymously, as *Money and Trade Considered: With a Proposal for Supplying the Nation With Money.* At least 15 other tracts with surprisingly similar titles appeared in the same year or early in 1706. Law and the authors of the other tracts all attributed the crisis to scarcity of money, but Law was the only one who carefully formulated the theory underlying his proposal. He explained that value is deter-

mined by supply and demand and that the value of money is only a special case in value theory. The key to his monetary thought is his assumption of a state of disequilibrium, with large masses of idle factors of production, as a starting point for analysis.

Law presented at least 24 numerical examples to show that if the money supply were increased by notes issued for productive loans, employment and output (and, implicitly, the demand for money) would rise proportionately and the value of money would remain stable. He also argued that the notes of the land bank would have other advantages over metallic money in that they would be easier to transport, store, and count, while being equally divisible without loss of value and equally capable of receiving a stamp as metallic money. Moreover, the supply of bank notes, unlike that of metallic money, would be perfectly elastic. Yet another advantage that Law attributed to his scheme was that it would prevent any adverse effect on the balance of trade. Assuming that the international demand for goods was perfectly inelastic, he argued that debasing the coinage and marking up coins would render the balance of trade unfavorable and induce an outflow of specie, while the introduction of notes would avoid this consequence. Nor would the notes, unlike debasement of the coinage, create inflation. Although Law's scheme was favored by the duke of Argyll, the lord high commissioner, and the earl of Islay, it won active support from only two members of the Scottish Parliament.

Back in France, in 1706 Law submitted to Chamillart his "Treatise on Money and Commerce" ("Mémoire touchant les monnoies et le commerce"). It was dated November 18, 1706, and has remained not only unpublished but unused even by scholars; yet it is the best single presentation of Law's monetary theory. A most interesting aspect of the document is Chamillart's extensive and often shrewd commentary in the margins; these comments are noteworthy because they show that Chamillart detected the error in Law's argument that debasing or marking up the coinage would render the balance of trade unfavorable. Law's proposals that France adopt paper money, as superior to gold and silver, led to his expulsion from that country. Allegations that he was banished because of his success as a gambler are unfounded.

In the winter of 1712 Law was in Turin and presented several tracts on money and banking to Vittorio Amadeo II, duke of Savoy, who was deeply impressed by Law's intellectual power and monetary knowledge but who decided against a bank.

Later the duke urged Law to return to Turin, presumably to establish a bank, but Law declined.

In December 1713 Law returned to Paris and was soon again plying the French government with proposals for a bank. In July 1715 he came very close to convincing Desmaretz, then finance minister, who rejected his project only because he could not stomach a bank that would be as completely dominated by one man as, he sensed, the proposed one would be dominated by Law. After the death of Louis XIV, Law convinced the duke of Orleans, the regent, of the desirability of a royal bank, and encountered his last defeat when the proposal was rejected by the Council of Finance on October 24, 1715. Shifting to the concept of a privately owned institution, Law obtained a charter for the General Bank, on May 2, 1716. It was the first Bank of France and the opening wedge for his System. The charter for the Bank was granted to "Mr. Law and his Company." Law drafted the charter and subscribed for one-fourth of the stock. As Desmaretz had anticipated, the bank was completely dominated by Law—more so than any other national or central bank has ever been dominated by one man.

From the outset the General Bank was conservatively managed. There is no evidence that it ever failed to meet an obligation. During the 31 months of its operation its notes raised the money supply only about 3 per cent, and its deposits were infinitesimal. The General Bank discounted accepted bills of exchange drawn on Paris at 6 per cent from June 1716 through March 1718, when the rate was reduced to 4 per cent. While the Bank's discount rate was 6 per cent, the modal market rate on secured loans at Paris was 5 per cent, and the average rate was a trifle lower. From April to December 1718 the market rate moved irregularly downward but did not reach 4 per cent. The General Bank may have exerted some slight downward pressure on the rate of interest, but it did not end "usury."

In the beginning the business of the Bank was confined to Paris; but in the summer of 1716 custodians of public revenue in the provinces were instructed to accept and redeem Bank notes, and on October 7 they were ordered to remit to Paris exclusively in these notes. Consequently, even in the Bank's first year, notes were circulating in distant provinces, and the Bank achieved a national circulation far more quickly than did any other public bank in Europe before the nineteenth century.

It was early in 1717 that Law first became involved in the financial scheme eventually known as the Mississippi Bubble (Louisiana being commonly

called Mississippi then). The financier Antoine Crozat, a neighbor and friend of Law's, decided to give up his Louisiana concession, having lost 1.25 million livres in four years. Convinced that only a company could raise the necessary capital, the government made no effort to dissuade Crozat. It was attempting to withdraw paper money from circulation; since this currency lessened confidence in Bank notes, Law favored deflating it. He thereupon devised a scheme to solve the government's financial problem and at the same time promote colonial trade—he proposed to establish a company to take over Louisiana and sell its stock for government paper money, to be converted into *rentes* and destroyed.

In August 1717 his Company of the West was chartered. Its shares were in denominations of 500 livres, and the capital was ultimately fixed at 100 million livres, payable in government paper money depreciated by about 60 per cent. Business was far better than in 1716, when the General Bank had been chartered, and many people believed that Louisiana offered possibilities of rich rewards. But they also knew that West India companies chartered under Richelieu and Colbert had failed miserably and that Crozat, one of the ablest and richest financiers in France, had just relinquished his Louisiana concession. Hence the stock was not fully subscribed until July 1718.

Thereafter the company's fortunes rose. In September 1718 it outbid all rivals for the lucrative monopoly on the importation, manufacture, and sale of tobacco, and in November it purchased the property and privileges of the Senegalese Company. Law was on his way. On May 26, 1719, the Company of the West absorbed the French East India Company and the China Company, thereby forming the Company of the Indies. In June the Africa Company was acquired.

Meanwhile, on December 4, 1718, the General Bank had been nationalized and its name changed to Royal Bank; nationalization was actually only a formality, since the crown had already bought 100 per cent of the stock. Control over the Bank remained in Law's hands, subject to approval by the regent (as had been the case up to that time). But notes could be issued only by royal decree and were guaranteed by the crown. In July 1719 the Company of the Indies was granted the right to farm the mints for nine years, and 25 of the 26 mints, the sole exception being the one at Lyons, became virtual branches of the Bank. In August, Law took over the general farm of indirect taxes, and in October he arranged for the Company of the Indies to refund the remaining public debt of 1,500 million livres at 3 per cent. On January 5,

1720, after having been "publicly" converted to Catholicism, Law became finance minister.

Law's System was complete, and he stood at the pinnacle of his power. After his fall he often said that he had had more power than any other uncrowned person had ever exercised in Europe, and he may have been right; for he controlled the colonial trade, the Royal Bank, the tobacco monopoly, the public debt, indirect taxes, and more than half of what is now the United States (excluding Alaska). In addition to being finance minister, he was the principal economic adviser and favorite of an absolute prince.

Law's India shares rose fiftyfold in about two years, most of the rise in the last half of 1719, when France experienced the greatest speculative orgy she has ever had. The first impetus to this speculative rise was the substantial profit from the tobacco monopoly; more important was Law's acquisition of the tax farm, since it was well known that many of the great fortunes in France had been made through tax farming. From the beginning Law encouraged speculation, and his advice was widely taken. Traders rushed in from the provinces and from many foreign countries. Hitherto prudent Frenchmen and even some families in other countries liquidated real property to buy Law's stock, and the mania extended down to the very poor, who staked their patrimonies and life savings on small fractions of shares. The *Nouveau mercure* of November 1719 reported that "some stockholders have died from surprise, others from joy, [while still others] have gone mad from calculating their profits." Law converted much of his own great fortune—most of which was a capital gain on his stock—into magnificent rural estates and town houses, thus advertising his wealth and whetting the public appetite for his shares. The speculative boom rested heavily on hopes of gain from the exploitation of Louisiana.

It was not only the exaggerated estimate of the natural riches of Louisiana that constituted an essential weakness of Law's System but also his conviction, which went back to at least 1702, that shares of stock are money. Believing this, Law pegged the price of his stock at 9,000 livres when it began falling in January 1720, thus not only monetizing the stock but making it a monetary standard. Sales of stock to the Bank far exceeded purchases, and the quantity of Bank notes in circulation rose so sharply that they occasionally fell below par in specie. On Law's initiative, pegging was discontinued by the stockholders on February 22, but a considerable decline in the price of Law's stock led to its resumption on March 20. Inflation was disastrous: from March 26 to May 1 note cir-

ulation increased by 1,470 million livres, or about 125 per cent, and during May the note issue reached a peak of 2,696 million livres. Pegging the stock cost more than the equivalent of half the public debt. (The government admitted in 1725 that the second round of pegging was ordered by the regent.) Commodity prices had risen more than 50 per cent in the major cities, and money wages lagged far behind.

Law then made a mistake that again derived from his erroneous belief that stock is money: he chose to deflate, rather than remove the peg on his stock. Although this deflation has been widely attributed to his enemies, a decree lowering the price of stock to 8,000 livres as of May 22, 1720, and by stages to 5,000 livres on December 1, was drafted by Law himself and corrected in his own hand. Bank notes were to be marked down 20 per cent on May 22 and by stages to 50 per cent by December 1. Consternation and panic reigned, intensified by an attempt by the Bank to collect all loans on stock. Yielding to the clamor of the populace, the regent dismissed Law, but this only increased the uncertainty. On May 27 the deflationary decree was repealed and the old rating of the Bank's notes restored, while the peg on stock was removed. The restoration of Law, at the end of May, to his former position in the Bank and the company was not accompanied by any restoration of public confidence, and his System was doomed.

From June to September of 1720, Law and the regent strove desperately to rehabilitate the System through drastic deflation of the Bank's notes. But the notes steadily lost favor, and by December the country had returned to a specie basis. In mid-December Law was permitted to leave France, and his tottering System collapsed.

Even Law's worst enemies and severest critics recognized that France had been suffering one of the worst crises in her history in June 1716, when the General Bank opened its doors. Commodity prices had been falling disastrously for a year and a half. Unemployment, bank failures, commercial bankruptcies, agricultural distress, and social unrest were rife. Pessimism filled the air. Law was at the head of a national bank and in a position to influence strongly the economic policy of an absolute prince. No other "Keynesian" economist has ever had such a golden opportunity.

What did Law accomplish? He not only ended unemployment but even induced a labor shortage and overfull utilization of plant capacity. Public and private obligations, hitherto chronically in arrears, were paid promptly. Despair gave way to

optimism. The population of Louisiana rose almost tenfold; the burden of taxation was lightened; sinecures were reduced, and many fetters to trade were removed.

Many of Law's achievements were lasting. There was feverish construction of buildings—including a substantial number of magnificent structures in the Place Vendôme in Paris erected by Law himself. Large numbers of skilled workers and technicians were brought from abroad to establish new industries and improve old ones. The books of the tax farm were rationalized, subfarming was largely eliminated, and the administration was simplified and unified. Reform of the tax system was one of Law's most durable achievements. Dreams of wealth from Louisiana focused attention on the New World. Reflections on a new people and a new culture enlarged horizons, bred tolerance, and prepared the way for the Enlightenment.

But these gains were not without cost. During the boom commodity prices rose about 100 per cent in Paris and Bordeaux, 170 per cent in Marseilles, afflicted in 1720 by one of the worst plagues in French history; and 140 per cent in Toulouse, also affected by the plague. Creditors, pensioners, and other holders of passive rights suffered cruel losses, and the average decline of daily real wages in Paris, Marseilles, and Toulouse was 25 per cent. Holders of the Bank's notes and of shares of the Company of the Indies presented more than half a million claims (nearly four-fifths of which were from the provinces) to the commission that liquidated the System, and losses in the liquidation ran as high as 95 per cent. (Even for those who could prove they had exchanged coins for notes at the Bank the loss was two-thirds.) Many families were ruined; most were hurt. A surprising number of very poor people suffered crushing losses on small fractions of shares. Thousands of noble and well-to-do families in foreign countries lost major portions of their fortunes.

Law made serious mistakes in theory and practice and undertook far more than anyone should have. However many of his ideas have stood the test of time, and his integrity has withstood all assaults.

LAWS, CONFLICT OF

See CONFLICT OF LAWS.

LE BON, GUSTAVE

Although Gustave Le Bon (1841-1931) is most generally known for his book *The Crowd*, his career in fact had three overlapping phases, the successive focuses of his interest being anthro-

pology and archeology, experimental and theoretical natural science, and only finally social psychology.

Le Bon received a doctorate of medicine without any vocation for the profession. He began his adult life with travels in Europe, north Africa, and Asia. From these travels there resulted a half-dozen books, chiefly on anthropology and archeology. The last of the works on these subjects, *Les monuments de l'Inde*, appeared in 1893, when Le Bon was 52.

However, when he was in his late thirties Le Bon's interests began to shift radically: he invented recording instruments (exhibited in 1878), studied racial variations in cranial capacity, analyzed the composition of tobacco smoke, published a photographic method for making plans and maps, as well as a treatise that put the training of horses on an experimental basis, and, finally, devoted more than ten years to research on black light, intra-atomic energy, and the equivalence of matter and energy. During this period, furthermore, Le Bon began the work in social psychology that was to become the predominant concern of the final phase of his career. *The Crowd* appeared in 1895, when he was 54.

It is, of course, chiefly by virtue of the works of this third phase that Le Bon belongs to the history of social science. But these works in social psychology have links not only with the books of the period of his travels but also with those of what might be called his scientific phase. Thus, when Le Bon dealt with pedagogy and politics, he carefully transposed to children and peoples what he had earlier learned about horses. Similarly, he claimed to support his ideas on the psychological hierarchy of races and sexes with material from his study of the variations in the volume of the brain.

Before sketching the main outlines of the doctrine underlying all of Le Bon's psychological work, one trait of this work—perhaps at the time the most original—should be stressed. He selected extremely concrete problems for study—for example, the socialist movement, the organization of education, colonial policy, the French Revolution, and World War I—but always sought to treat these problems in terms of scientific generalizations at the highest level of abstraction. This was nothing less than an attempt to synthesize Comte and Spencer with Michelet and Tocqueville. Le Bon was convinced that contingent events as well as social behavior are guided by eternal laws (1912, p. 322).

The unconscious. One of these eternal laws that Le Bon constantly invoked is the futility of rationality in the affairs of society: an idea does not prevail because it is true, but by virtue of psychological mechanisms that have nothing to do

with reason, such as repetition and "mental contagion." These mechanisms permit an idea to penetrate into the unconscious, and it is only when an idea does become part of the unconscious that it becomes effective for action. This rudimentary theory of learning was first formulated when he was studying the training of horses and then extended to human education and to politics. His watchword was: let the conscious become the unconscious.

The principle that only the unconscious produces effective action applies, according to Le Bon, not only to individuals but also to whole peoples (or races, so long as it is well understood that what is meant are "historical races," created by the events of history, and not races in the anthropological sense). Thus a people, or a civilization, or a race, properly so-called, must have a national soul, that is, shared sentiments, shared interests, and shared ways of thinking. The national soul is produced by such nonrational mechanisms as suggestion and heredity; all metaphysical, religious, political, and social beliefs are so rooted in the national soul of each people. It is these deeply-rooted beliefs that govern institutions (not the inverse, as Tocqueville had imagined).

The vital implication of this theory for politics is that laws are illusory and ineffective if they lack a basis in the national psychology. Moreover, according to Le Bon, it is these fundamental beliefs that produce lack of understanding and intolerance between peoples and groups and thus account for the irreducibility of what may be called ideological conflicts and the inevitability of civil strife and international wars.

Hierarchies. Le Bon was perennially establishing hierarchies. Thus he asserted the existence of a hierarchy of races, based on psychological criteria (such as degree of reasoning ability, power of attention, mastery over instinctual drives; see the *Psychology of Peoples* 1894) and confirmed on anatomical grounds by the alleged greater differentiation of the superior races and the greater consequent incidence of individuals who rise above the mean. As a specific instance of such hierarchical ordering, Le Bon repeatedly compared the mental constitution of the Anglo-Saxon race with that of the Latin peoples, and down to World War I he considered the Anglo-Saxons superior in every way. He established a hierarchy of the sexes using the same kind of criteria. According to his system of evaluation, animals, the insane, socialists, children, degenerates, and primitives were inferior beings.

The crowd. He postulated another, very interesting kind of inferiority: this is the inferiority of

the crowd, or of man in the crowd. Le Bon believed that the psychology of men in a crowd differs essentially from their individual psychology; they become simple automata, instances of a sort of new being. Their spirit is that of the crowd which, like every spirit, is part of the unconscious; but this is a very low-level part of the unconscious, archaic or primitive from a historical point of view and medullar from a physiological one.

The psychological characteristics of crowds, as analyzed at length in the celebrated *The Crowd*, may be grouped around three themes. The first and most general characteristic attributed by Le Bon to crowd behavior is that of unanimity; he called this the law of the mental unity of crowds and asserted it as a dogma. He saw this mental unity accompanied by an awareness of unanimity that has important consequences: dogmatism and intolerance, a feeling of irresistible power, and a sense of irresponsibility. The second characteristic of crowd behavior is its emotionality: the actions of the crowd are sudden, simple, extreme, intense, and very changeable, so betraying the feminine nature of crowds. The third descriptive theme is that the intellectual processes of crowds are rudimentary and mechanical: crowds are very credulous, their ideas are schematic, and their logic is infrarational and ignores the principle of non-contradiction.

How, then, does it happen that in a crowd situation even the most rational of men are transformed into brutes? Le Bon, like Tarde, who wrote on the same topic at the same time, offered two explanations: mental contagion and the role of leaders, who are often, but not always, described as agitators. But what do these explanations amount to? "Contagion is a phenomenon that is readily observed, but has not yet been explained, and had best be related to the phenomena of hypnotism . . ." (1895, p. 17). "The unconscious minds of the charmer and the charmed, the leader and the led, penetrate each other by a mysterious mechanism" (1910, p. 139). These tautologous passages suggest that on occasion Dr. Le Bon knew how to resort to the technique of the doctors in Molière.

To concentrate criticism on this particular problem of explanation would be misleading, for these theories of mental contagion and of the role of leaders are no more gratuitous, no more confused, and no more based on obsolete psychology than is the entire core of Le Bon's system. They may even have special merit, for it was precisely such arbitrary assertions of Le Bon that contained his happiest insights. He believed that "the action of a group consists mainly in fortifying hesitant beliefs. Any individual conviction that is weak is rein-

forced when it becomes collective" (1912, p. 102); or that, during World War I, "isolated individuals regained their military value when they rejoined a familiar group, but not when they were merged into other groups" (1916, p. 243). These are sentences that would not surprise us if they appeared in *The People's Choice* or in *The American Soldier*.

The fact remains that these two sentences went unnoticed. It was by the most reckless, the most false, and the most harmful of his theories that Le Bon exerted his greatest influence, in France and even more so abroad. In particular, the "law of the mental unity of crowds" was widely accepted and taught, and perhaps still is. Ironically, the fame of some men is based on their mistakes and thereby confronts their critics with a painful dilemma: either to blame such a man for the very things that made him popular or to praise him for contributions that would not have existed were it not for the mistakes.

JEAN STOETZEL

 PICARD, EDMOND 1909 *Gustave Le Bon et son oeuvre*. Paris: Mercure de France.

LE PLAY, FRÉDÉRIC

Frédéric Le Play (1806–1882), French sociologist, is best remembered for his development of a method of research and data presentation known as the monographic method and for his classification of families into patriarchal, stem, and unstable types. His ideas had an important influence on European sociology from about 1860 to 1940, and his work is still a major inspiration to Roman Catholic sociologists. Many concepts developed by Durkheim can be found in their initial crude form in Le Play's work.

Le Play was born in Normandy, the son of a petty customs officer. His father died when Le Play was only five, and shortly afterward he went to live with a rich uncle in Paris. Here, as he grew up, he became an avid listener to the intellectual discussions that took place in his uncle's salon. Le Play, however, was never to forget the harbor town of his birth. He seems to have greatly idealized the frugal existence his family led during the difficult years of the Napoleonic blockade; this may help to explain why, when he came to consider such problems as the maintenance of order, the avoidance of violence, and the demoralization of the poor, it was not in the increase of the standard of living that he saw the solution but in the strengthening of family ties.

Social philosophy

Le Play wrote his main work, *Les ouvriers européens* (1855), between 1829 and 1855. At that time a large section of the bourgeoisie had developed a fairly durable synthesis of aristocratic and bourgeois values. Abandoning Voltairean skepticism, it had adopted a largely ceremonial Catholicism, tempered by mild anticlericalism and theological indifference. The only dynamic elements in this outlook were respect for hard work and a stress on the need for rootedness (*enracinement*) in the locality of one's birth—a rootedness consecrated by the ownership of private property.

Few counterinfluences disturbed this prevailing climate of thought. The followers of Saint-Simon still constituted a very articulate intellectual minority, and it was in reaction to one of them, with whom Le Play traveled through Europe, that Le Play was led to develop and systematize the beliefs and attitudes instilled by his upbringing. For the Saint-Simonians, centralist and deductive in their approach, social disorder and pauperism were to be solved through the complete reintegration of society around the industrial order. Property was to be controlled by the industrialists (the cre-

ators of wealth), rather than by inheritors, and the industrialists were to be helped—"guided," Auguste Comte would say—by the priests of the positive science of society. The problem of power relations would be solved by the obviousness of right reason. Reason would organize the world, control nature, and promote progress, with the happiness of the individual following naturally from the welfare of society.

Le Play rejected this technocratic and optimistic view. He decided that there is no such thing as unilinear social progress—there can only be cycles of prosperity and corruption, the former inevitably engendering the latter. People in simple societies, like the fishermen of his childhood or the gentle folk of the Harz, may attain peace and contentment, but people in complex societies cannot escape strife and misery. Le Play believed that man has always known that the supreme good lies in social peace, on the one hand, and moral conduct, on the other; this was codified once and for all in the Decalogue. How, then, can one speak of inevitable progress when the principles of the Decalogue may have been followed in earlier periods of history only to be ignored in later ones? The best that could happen would be a revival of what has always been acknowledged to be the truth. The happiness of man does not reside in increased comforts and education but in recognizing the soundness of these principles of good conduct, in spite of the seductiveness of false doctrines, and in conforming his life to them.

It is interesting to note the dual orientation of Le Play's thought. There is, on the one hand, the importance of having the right ideas—a typical French approach, which culminated in the concept of the idea-force of the late-nineteenth-century psychologists and which was not without influence even on Durkheim. And yet, on the other hand, there is the belief in the effectiveness of sheer coercion when practiced by the righteous to preserve lesser men from temptation. It reflects the Roman Catholic oscillation between the stress on individual free will and the need for the church to protect man from himself. The function of the social scientist is to fight against false doctrines and through the use of the scientific method to prove the soundness of the simple eternal truths. Another interesting aspect of Le Play's thought, differentiating it from Saint-Simon's, Comte's, or Tocqueville's, is its resolutely homocentric quality: he focused upon the problem of individual happiness—or salvation, as a Puritan might say—rather than upon the "utility of the community," as Pareto was to phrase it. The use of the word "happiness"

(*bonheur*) is not accidental either, and Durkheim used this concept later in his discussion of anomie: *bonheur* is a state of inner harmony, with a definite sensualist tonality, rather than an external goal, like salvation. And *bonheur* is to be gained through control over man's essentially base nature (Durkheim would later speak, more neutrally, of the animal nature of man in contrast to his social nature). To achieve this control, man has as allies a divine force, the grace of God, and a social force, the family. When population size and density reach a certain level, thereby creating more complex problems of control (the exact terms of the equation are left unclear, but the critical level seems related to a more complex division of labor), the church and the state are to assist the family in its task. Insofar as men acting collectively can have any impact upon the happiness of the individual, they can do so only through the strengthening of the family.

Since industrialization had created pauperism and a rootless, marginal type of working class, the members of which were at the mercy of their base passions, the control and reintegration of that working class into the community of the righteous would be secured only by the consolidation of the working-class family and, more immediately, by its assimilation into the entrepreneur's family through the institution of patronage. Then the individual worker and his kin would have once more an opportunity for *bonheur*. Where Durkheim was to offer the professional organization as a means of alleviating the anomie that prevailed in economic life—a recommendation commonly made by French intellectuals, unless they belonged to the somewhat marginal Manchesterian group of Molinari—Le Play offered the family firm, in which the sting of the power relationship was removed by the fusion, in paternal-type relationships, of power with love. The rootlessness of the urban working class might be overcome through the device of permanent labor contracts and the fostering of property ownership by workers.

Le Play's theoretical interest in the variety of income sources in the workingman's budget (see Parsons et al. 1961, pp. 457–459) not only shows he rejected on empirical grounds the definition of working-class status as the nonownership of the means of production but also suggests his concern for a program of social action. The budgets itemized by Le Play often show the worker's family securing "profits" from home industries of which family members are the sole customers (owning a cow, rather than buying milk on the open market). Ideally, instead of private property being abolished,

as advocated by the socialists, its ownership should be diffused, and more immediately, the workers should be encouraged and assisted by the entrepreneur in securing home ownership, since the latter is strategic to family stability.

Le Play's conception of the way in which the industrial world should be organized fitted very well with the romanticized version of the French family firm. He believed that in return for fealty and a nonbargaining approach to the labor contract, the family firm protected the worker from the vagaries of the market, through a conservative investment and sales policy—restricting expansion in times of boom and stretching out employment in times of depression, protecting the worker's family from want by provision of easily purchased homes and gardens and free social services.

The function of the employer, according to Le Play, was not so much to raise the standard of living of the worker as to provide him with moral leadership, help him acquire private property, and stimulate in him "the respect of the laws governing the family" (1864, vol. 2, p. 28). Property, in this context, whether house, land, or factory, is a visible symbol of the family, of its continuity and its moral fervor, rather than a mere means of production. Complete testamentary freedom is necessary to permit the transmission of family property, in its entirety, to the most deserving heir and, even more important, to prevent the destruction of the stability of the family itself. Not only may a parceled-out homestead be economically unviable but the breaking up of the estate will foster a break in the sibling solidarity, so indispensable to the preservation of the sound family structures, i.e., the patriarchal family and the stem family (for definitions, see below).

Le Play realized that the preservation of integral estates, the moral importance of which he had established, was in conflict with rules of the Code Civil, which enforce practically equal division among heirs. In his opinion, families faced with this dilemma had resolved it through a reduction in their fecundity, so that equal division would not destroy completely the holdings accumulated through years of hard work and thrift. This is his explanation for the decline of the French birth rate.

This deceptively simple mechanism—a bad decision by jurists may have widespread consequences for the reproduction policy of millions of families—underlines Le Play's belief in the power of good or bad political decisions to effect broad changes in the society in a one-way causal chain. Although this attribution of far-reaching demographic consequences to the Code Civil became widely popular,

it was, in the main, erroneous. The tendency to divide estates equally had existed in French families prior to the enactment of the Code Civil. Even aristocratic families, before the French Revolution, as Le Play's disciple Paul de Rousiers showed in the history of his own family (1934), tended to give equal shares to their children: Equal love for one's children must be symbolized by equal shares of property. Therefore, it was not inheritance laws that were responsible for the restriction of fecundity—such laws could be bypassed by any father who was able to make his children internalize his own conception of the importance of integral estates—but instead the relatively high degree of social mobility present in French society after the revolution.

Nevertheless, we can readily understand the great success of Le Play's ideas among the provincial aristocracy and among that section of the bourgeoisie which aspired to assimilate aristocratic patterns and protect its dynasties from the vagaries of the market and the competition of "upstarts." Strictures against the growth of central state power, suspicion of intellectuals, respect for local notables, belief that men are born unequal in their capacity to resist evil or do good—all this was highly pleasing to the *bien-pensants*. No wonder that for a century Le Playism has been a basic ideology for that group, becoming a major element in the development of one brand of Christian socialism; it is a most plausible version of conservative mythology, and its influence extended to Russia, Great Britain, Holland, Germany, and French Canada.

Le Play's sociology

So far we have dealt only with the ideological component in Le Play's work. But important though this is, it should not be allowed to obscure Le Play's major contributions to the growth of sociology as a science. These contributions cover three major areas: the theory of social control, the theory of social change, and research methodology.

Social control. For Le Play, the family is the chief agency of socialization and social control. The chances for the abuse of power that are inherent in any system of social control are here limited by the love of the parents for their children, who, in return, endure frustration more easily when it is meaningfully related to the family's welfare. The church and the state can at best only assist or complete the work done by the family in checking the base impulses of the child's raw nature. Indeed, the weaker the central government, the better is the opportunity for the family to develop its authority and improve its performance.

Le Play distinguished three main types of family structure: the patriarchal family; the unstable family; and an intermediate type, the stem family. In the patriarchal family the father characteristically keeps near him all his married sons and exercises supreme authority over them and their children. Property remains communal. The patriarch directs all work and accumulates whatever savings can be gathered once the traditional needs of all family members have been satisfied. Le Play saw this type of family as common among the pastoral peoples of the Orient, the Russian peasantry, and the Slavs of central Europe.

Le Play's unstable family resembles what is today called the isolated nuclear family. It is unstable because it has little resiliency in the face of economic hardship. It is typical of the industrial working class and is also to be found among the upper classes, mainly because of successional laws that compel the division of estates among heirs. Although this type of family permits a brilliant individual to gain great success, it compounds the risk of failure for the untalented.

The stem family is a type of patriarchal family in which only one of the heirs is retained in the family homestead; the others receive some form of dowry that enables them to establish themselves elsewhere. Nevertheless, for those who leave, the family homestead remains a ceremonial center, as well as a port in a storm. Thus, the stem family combines some of the flexibility and recognition of talent of the unstable family with the continuity and security of the patriarchal family.

Social change. Le Play's theory of social change is essentially dualistic. On the one hand, he attached enormous importance to beliefs and ideas; on the other, he seemed to stress a sort of technological determinism, rooted in the geographic environment.

Religious belief was given an especially important part in Le Play's theory of social change, although differences between individual doctrines were of little consequence to him. All human societies, he asserted, accept some form of the Decalogue, belief in which is a fundamental condition for the maintenance of order and solidarity. When these beliefs weaken, the society suffers—and when they vanish, the society vanishes with them. The diffusion of areligious and/or antireligious doctrines by intellectuals was, therefore, a major source of social disorganization; so were erroneous laws regarding succession, which made it difficult for families to maintain the continuity of the family estate; or political decisions such as those of Louis XIV regarding the centralization of the French

state; or beliefs, such as Rousseau's, in the inherent goodness of human nature. Such errors only show man incapable, of his own free will, of availing himself of the wisdom contained in the Decalogue. But these errors are a contingent factor, like the presence or absence of elite personalities—Plato's "divine men"—who create peace and order around them (and whom Le Play thought to be the best sources of information for the researcher). What can be taken for granted is that men will remain vulnerable to these errors, as well as remaining unequal in their capacity to create harmony around them.

The only causal process in history of which Le Play was certain was that prosperity always leads to the corruption of the elites, which leads in turn to the corruption of society. Corrupt social orders are purged by wars, which permit the more virtuous populations to assume political control over the more corrupt ones. The measure of this corruption is essentially the decline of paternal authority and the move away from the patriarchal and stem forms of family pattern toward the unstable form. Le Play's theory of social change belongs with the pessimistic, cyclical theories rather than with the optimistic, unilinear ones.

In contrast to the religious factor in social change or the impact of leadership and prosperity—which are essentially unpredictable in their incidence, if not in their consequences—the relationship between the family and its physical environment, as mediated by work patterns, seems to provide causal regularities susceptible of scientific inquiry. Steppe areas tend to produce stable patriarchal families; coastal fishing areas, stem families; and forests, unstable families (unless there happens to be rational exploitation of timber resources). Agriculture, if combined with proper succession laws, permits patriarchal families but usually produces stem families. The factory system, on the other hand, encourages unstable families among its workers, especially if the entrepreneurs do not fulfill their obligations of patronage. This was a major source of corruption in the prosperity engendered by industrialization.

Methodology. The monographic method is usually considered to be Le Play's unique contribution to the development of social science. Indeed, this method marks a twofold departure from the prevailing type of social science writing: first, it stresses immediate contact with the field data, collected with an eye to measurement, rather than relying on historical data or shrewd observations, as did Tocqueville or Taine; second, as Sorokin pointed out (1928, pp. 63–98), it introduces a

selective principle for the collation and presentation of data that is derived from a theoretical schema—the primacy of family relationships in controlling behavior, the dependence of family relationships upon certain aspects of the environment and especially upon those which determine the type of work the family engages in, and the belief that all crucial family activities express themselves in a monetary form, which can be represented as a budget item.

No doubt the monographic method developed from the type of systematic reports that students of the School of Mines were supposed to make on their field trips, with emphasis upon those items which could be tabulated and counted. Another intellectual influence was the surveys and inquiries which were commissioned by the parliaments of France and Great Britain. And about the same time Le Play began his field work, Villermé was conducting his inquiries on poverty in French cities.

The unique thing about Le Play's method is that his work contains the beginning of statistical techniques which later led to sampling, as well as the beginning of index construction. (The family budget was used because it permitted accurate computation, and the rigorous itemization of budgets is probably the reason why the *Ouvriers européens* received a prize from the Académie des Sciences in 1855). However, the monographic method, as Le Play used it, was in fact a rejection of the system building of Saint-Simon and Comte, rather than an effective commitment to inductive and experimental thought. Le Play was turning the positivist approach against its inventors because he believed that in his day only scientific descriptions of social realities would render self-evident the one way to social harmony and individual happiness. For him social science was not a cumulative body of theoretical propositions; it was simply a way to make evident the eternal laws of social peace. If abstract reasoning should lead to statements that contradict these laws, then the reasoning must be false. And although Le Play at one time seemed to draw an analogy between fact gathering and parliamentary representation, he did not see the necessity for systematic sampling, because he felt that a few monographs were sufficient to convince the reader of the correctness of these basic moral laws. The accumulation of data is more a rhetorical device than an attempt at inductive proof. In order to verify the results of direct observation, one should consult with local leaders, who are best equipped to describe and interpret local customs and events.

The paradox of Le Play's methodology is that it

is the invention of an antiempiricist. This inherent contradiction may explain why it failed to make as significant an impact upon scientific sociology as one might have expected.

Diffusion of Le Play's ideas

After the *Ouvriers européens*, Le Play turned essentially to propagandizing for social reform. Although he invoked the authority of the scientific method, rather than its logic, it is likely that he did render social science an important service by making the field of study a respectable one for the gentleman scholar, even though it meant contact with the lower classes in a context that precluded appropriate deference.

Le Play's follower Henri de Tourville was to complete the monographic method in 1886 by drawing up a "nomenclature"—a sort of sequential checklist for describing the relationship of the family to its social and physical environment. The items to be covered were place, work, property system, forms of wealth, remuneration, savings, and the major social categories and organizations with which the family must deal—neighborhood, formal organizations, community, city, province, state, racial group—in essence, the outline of what was to become known as the community study.

However, the duality of Le Play's thought—idealist in its emphasis upon religious values, positivist in its emphasis upon geography and technology—led in 1886 to a split between his followers. The idealist component was developed into a predicating type of analysis, most notably by Charles de Ribbe, and again, more recently, into a philosophical-aesthetic type of essay writing, best exemplified by the work of Jean Lacroix.

The positivist group, represented by Tourville, de Rousiers, Robert Pinot, and Edmond Demolins, focused much more on the elements of a theory of the social system that were already implicit in the famous "nomenclature." Some, like Demolins, became much more openly positivist and stressed the geographical aspect of Le Play's theory of social change. They refused to condemn the industrial order as the source of social disorganization and came to challenge the belief that the stem family was the highest form of moral life. For them the model family was the "particularist" type, which they saw predominating in Scandinavian and Anglo-Saxon countries and which is essentially an optimistic version of what we would now call the isolated nuclear family. De Rousiers in particular, who visited the United States, gave the American family a good share of the credit for American enterprise and progress (see 1892). The analysis made by

the positivist group of the relations between family type, on the one hand, and forms of government, types of economy and managerial policies, general styles of formal and informal organizations, and the school system, on the other, are often amazingly insightful and modern in content.

Neither wing of the Le Play school, however, had much impact upon French academic sociology, which was controlled by middle-class, anticlerical Durkheimians. The Le Play school was Roman Catholic and upper class in orientation. In fact, many of its members were aristocrats, for whom the field techniques of the monographic method, far from implying a threat to their social status, represented both a novel way of reaching out benevolently to the masses and an endorsement of the "facts," rather than a submission to the "theories" of bureaucrats or professors. The method fitted the antirational ideology of the traditional French upper classes, as displayed, for instance, in their predilection for the metaphysical philosophy of Henri Bergson.

This rejection of theory was the key weakness of the monographic method. It accumulated data which are supposed to speak for themselves but which, in the absence of comparative perspectives, say relatively little. However, the contemporary sociologist who wishes to compare these data with present-day equivalents will find in the monographs of the Le Play school a rich lode of "sociological fossils."

Influences on the literature. The first edition of the *Ouvriers européens* was published in 1855. "In order to avoid upsetting public opinion," it was published as a limited luxury edition, and the government presses in Paris handled the printing. The second edition was published in Tours in 1879, by the Mame publishing company, well known in France for its specialization in Roman Catholic literature.

The books that Le Play published after the *Ouvriers européens* are fundamentally works of special pleading, although claiming to be based on his past empirical research. The main ones are *La réforme sociale en France* (1864), *L'organisation du travail* (1870; an English translation appeared in 1872), *L'organisation de la famille* (1871a), *La paix sociale après le désastre* (1871b), *La constitution de l'Angleterre* (1875), and *La réforme de l'Europe et le salut en France* (1876). Part of Le Play's correspondence was published under the title *Voyages en Europe, 1829-1854: Correspondance* (1899).

A fairly extensive bibliography of Le Play's works can be found in *Textes choisis* (1947, pp.

59-60). Partial translations of the *Ouvriers européens* into English are to be found in Zimmerman and Frampton's *Family and Society* (1935, pp. 359-595). Extracts have been translated and reproduced in Riley's *Sociological Research* (1963, vol. 1, pp. 80-90) and in Parsons and his associates' *Theories of Society* (1961, pp. 457-459).

In 1856 the Société Internationale des Études Pratiques d'Économie Sociale was founded, with L. R. Villermé as its first president. It published a bulletin of its proceedings and in 1857 brought out ten volumes of "monographies" under the title: *Les ouvriers des deux mondes*. The bulletin of the society became in 1881 a review called *La réforme sociale*. This journal was conservative, Catholic, and largely anti-industrial. One of the better representatives of that tendency was de Ribbe, whose *La famille et la société en France avant la Révolution* (1873) is fundamentally a work of moralizing ideology.

Dissatisfied with the orientation of *La réforme sociale*, a group composed of Demolins, Tourville, de Rousiers, and Robert Pinot broke away in 1886 and founded *La science sociale*, under the editorship of Demolins. (In 1935 *La réforme sociale* and *La science sociale* merged to become *Les études sociales*.)

Among the works of the *Science sociale* group one may cite Demolins's *Les grandes routes des peuples: Essai de géographie sociale, comment la route crée le type social* (1901-1903). A more popular book by the same author was translated into English in 1898 (see 1897), with the title *Anglo-Saxon Superiority: To What It Is Due*; it ascribes the putative superiority of the Anglo-Saxons over the collectivistic societies of France and Germany to the particularistic family system and its stress upon self-reliance, progressive education, a responsible elite, and a noninterfering government. A crucial interest of Demolins was indeed education, which he wanted to reform along the lines of the English public school system. He founded the only successful progressive school that France has known, and it is described in his *L'éducation nouvelle: L'École des Roches* (1898).

Tourville was the theoretician of the *Science sociale* group. His most important work, besides the refinement of Le Play's nomenclature, was translated into English in 1907 as *The Growth of Modern Nations: A History of the Particularist Form of Society* (1905).

One of the most interesting writers of the *Science sociale* group was de Rousiers. He wrote one of the best statements of the group's position in his article "La science sociale," published in the

Annals of the American Academy of Political and Social Science (1894). His *American Life* (1892) and *The Labour Question in Britain* (1895) are among the best products of the Le Play school. In *The Labour Question* the monographic method reaches a new level of sophistication, through effective comparisons between the families of wage earners in different industries and between different types of productive organizations. Note also de Rousier's *Hambourg et l'Allemagne contemporaine* (1902), which brings a needed correction to Demolins's strictures on Germany as a collectivistic society, and *Une famille de hobereaux pendant six siècles* (1934).

Sociologists who wish to use monographies for a comparative historical perspective will consult with profit the extensive bibliography in Ferré's *Les classes sociales dans la France contemporaine* (1936, pp. 231-262), in particular the works of Jacques Valdour, who used participant-observer techniques. An addition to the Ferré bibliography should be the white-collar budgets in Henry Delpech's *Recherches sur le niveau de vie et les habitudes de consommation* (Toulouse 1936-1938) (1938).

One of the more fruitful uses of the budget method was made by the Durkheimian Maurice Halbwachs and is summarized in his work *L'évolution des besoins dans les classes ouvrières* (1933).

The most interesting offshoot of the Le Play school has been the work of Philippe Ariès, who has attempted to synthesize its approach with that of the Durkheim school, using a comparative historical approach rather than a strictly monographic one. His most important works are *Histoire des populations françaises* (1948) and *L'enfant et la vie familiale sous l'ancien régime* (1960), which was published in English as *Centuries of Childhood: A Social History of Family Life* in 1962.

Among commentaries on Le Play and his school must be cited Sorokin's *Contemporary Sociological Theories* (1928, pp. 63-98), *Recueil d'études sociales publié à la mémoire de Frédéric Le Play* (1956), and "Les cadres sociaux de la doctrine morale de Frédéric Le Play," by Andrée Michel (1963).

LEADERSHIP

- I. PSYCHOLOGICAL ASPECTS
- II. SOCIOLOGICAL ASPECTS
- III. POLITICAL ASPECTS

Cecil A. Gibb
Arnold S. Tannenbaum
Lester G. Seligman

PSYCHOLOGICAL ASPECTS

The concept of leadership, like that of general intelligence, has largely lost its value for the social sciences, although it remains indispensable to general discourse. There is a great variety of ways in which one individual stands out from others in social situations and in which the one may be said, therefore, to be "leading" the others. So diverse are these ways that any one concept attempting to encompass them all, as "leadership" does, loses the specificity and precision that is necessary to scientific thinking. To call someone a leading artist may mean only that as writer or painter he enjoys greater public acclaim and probably greater sales than do others similarly engaged; but it may also mean that others are aware of him and that in subtle ways he exercises an influence upon them. In general, it is an essential feature of the concept of leading that influence is exerted by one individual upon another, or more commonly, that one or a few individuals influence a larger number. Influence, however, is itself a nonspecific term. One may be influenced by another's disapproved-of behavior to act antagonistically toward him or in a direction quite contrary to that he represents or advocates. It is usual in such circumstances to say

that one is driven to act thus, rather than led. "Leading" implies a shared direction, and this, in turn, often implies that all parties to the leadership relation have a common goal or at least similar or compatible goals; and as Hollander and Julian (1964) say, "leader influence suggests a positive contribution toward the attainment of these goals." Thus, any act of leading implies an interindividual relationship, and leading is one form of interindividual influence. Definition of the simplest unit of analysis in leadership as "the act of leading" has led to the identification of four basic elements in the relationship: (1) the *leader*, with his characteristics of ability and personality and his "resources relevant to goal attainment" (Hollander & Julian 1964); (2) the *followers*, who also have relevant abilities, personality characteristics, and resources; (3) the *situation* within which the relationship occurs; and (4) the *task* with which the interacting individuals are confronted. The nature of the leader-influence relationship and the characterization of the act of leading are to be understood in terms of interaction between these four sets of variables, each of which requires modest amplification.

The leader. Acts of leading may be very brief and of varying importance for long-term interaction, but the concept of leader implies a role relationship of some duration, although this duration is not so great or the role so unvarying as is often thought. A leader, however, is one who is repeatedly perceived to perform acts of leading. As Sherif (1962) points out, generally the leader position is occupied for a considerable time by the same individual. While what has been said thus far holds equally for animal and for human social action, the greater complexity of human interaction and our more detailed knowledge of the communication processes involved in it enable us to pursue this discussion more deeply if particular attention is paid to human interaction.

The group. It is appropriate here to introduce the concept of groups and to discuss leading as action occurring in groups.

The term "group" refers to two or more individuals interacting in the pursuit of common or compatible goals in such a way that the existence of many is utilized for the satisfaction of some needs of each (Cattell 1951; Gibb 1954). Leading may therefore be said to occur only within groups, and a leader may be seen to occupy a position within a group and to fulfill a group role. The principal characteristic of this role is that its occupants are accorded a high proportion of the group's resources of time and attention and are expected

to perform a high proportion of initiating, decision-making, or leading acts; there is a disposition to "follow" them. Given agreement with these principles, there is still room for a variety of approaches to the identification of leaders in specific groups. Fortunately these different approaches do not frequently lead to identification of different leaders in a given group at a given time, but they do represent different emphases. One widely used approach, which owes much to the work of Hemphill (e.g., 1949), identifies leaders in terms of the relative frequency with which they perform defined acts of leading. This approach recognizes the fact that groups develop leadership hierarchies and that differentiation between successive levels is primarily in terms of frequency of leading. Only rarely, and then in highly structured organizations, does such an approach identify "the leader." Most groups have many leaders, and differentiation between leaders and followers is a question of drawing an arbitrary line on a frequency continuum.

A second approach seeks those who exercise influence (in a shared direction) over other individuals. It has been shown (Gibb 1950) that leaders may be reliably identified in terms of the extent of such influence, and this form of definition has been employed frequently. In an unpublished study Seeman and Morris (1950) suggested one possible definition of leadership that emphasizes the aspect of influence: leadership acts influence other persons in a shared direction. The position of leader is then defined in terms of relative degrees of influence.

One of the earliest definitions, still widely adopted, is that of Pigors (1935), who indicated that leadership is a concept applied to the personality-environment relation to describe the situation when a personality is so placed in the environment that his "will, feeling and insight direct and control others in the pursuit of a common cause."

An important variant of the influence criterion has been proposed by Cattell (1951). It is his suggestion that the measure of a leader's influence is to be sought not so much in his influence on other group members but in his influence upon total group locomotion or group "syntality" (characteristics, nature, or quality, analogous to individual personality), which is judged from the effectiveness of total performance of the group as group. While this view has important implications, it does not necessarily lead to different leader identification than the other approaches.

The source of power. Cutting across these considerations in the identification of leaders in a group, and contributing significantly to the defini-

tion of the concept of leading, is the essential question of the source of the power to influence. The point at issue here will be understood most readily if thought is given to a group within a larger organization. Power within such a group frequently resides, in whole or in part, in a person appointed by the parent organization to exercise a power delegated to him by that organization. That such a person exercises influence over other group members, there can be no question; but the sources of the power, the nature of the relevant and effective sanctions, and the nature of the relation between influence agent and recipient are in this case qualitatively very different from those to be observed in a voluntary group or association. There seem to be specific advantages for clarity in maintaining this distinction (Pigors 1935) and in using the term "headship" for the former, reserving "leadership" for the latter only. While many characteristics differentiate headship and leadership (Gibb 1954), most basically these two forms of influence differ with respect to the source of the authority. In Sherif's words, "the leadership status itself is within a group and not outside of it" (1962). The leader's authority is spontaneously accorded him by his fellow group members, the followers. The authority of the head derives from some extragroup power that he has over members, who cannot meaningfully be called his followers. They accept his influence on pain of punishment derived from the larger organization, rather than following him in the promise of positive satisfaction derived from the achievement of mutually compatible goals. It is not suggested, of course, that headship and leadership are mutually exclusive, but neither are they coincident, as so much popular thinking suggests. It is a most significant consideration that, as Sherif (1962, p. 17) recognizes, "the leader is not immune from group sanctions if he deviates too far from the bounds of acceptable behavior prevailing in the group," while a head is independent of sanctions applied by the group, though he will in turn, of course, be subject to those applied by the larger organization to its members occupying this particular status. Thus, there is a sensitivity to the interaction between leader and followers that is not necessarily present in that between head and subordinates.

The followers. Probably the most important thing to be said about the concept of followers is that they, too, fulfill active roles. They are not to be thought of as an aggregation minus the leaders. It is part of the intention of the group concept to imply that all members actively interact in the course of movement in a common direction. Lead-

ers and followers are collaborators. The concepts of leading and following define each other. There can be no leading without following, and of course, no following without leading. Not all members of any given group will, at any particular time and with a particular leadership, be followers, but all members will at some times, under some conditions, be followers or they will forfeit their membership. Neither are followers exclusively confined to this role, any more than leaders are exclusively and always engaged in acts of leading. In fact, leaders and followers frequently exchange roles (Hollander 1961), and observation has shown that the most active followers often initiate acts of leading. Hollander and Julian (1964) suggest that it is an error to speak of an influence agent and an influence recipient as if they were distinct from one another, and this is well supported. The expectations of the follower and the acceptance he accords the leader may be as influential in the production of the act of leading as are the resources of the leader himself. This relation, although rather more subtle and less well taught, may be quite as important as the reciprocal sex roles so readily observable in any society.

The situation. The term "situation" is used here to mean "the set of values and attitudes with which the individual or the group has to deal in a process of activity and with regard to which this activity is planned and its results appreciated. Every concrete activity is the solution of a situation" (Thomas & Znaniecki [1918] 1947, p. 76). The elements of the situation are (1) the structure of interpersonal relations within a group; (2) the characteristics of the group as group and taken as a unit; (3) the characteristics of the larger culture in which the group exists and from which group members have been drawn; (4) the physical conditions within which the group finds itself constrained to act; and (5) the perceptual representation, within the group and among its members, of these elements and the attitudes and values engendered by them. The situation is especially liable to modification through changes in interpersonal relations, the entrance of new members and departures of others, changes in physical conditions, and the like, which alter action possibilities and, consequently, the perceived probabilities of goal attainment or assessments of costs. Research (Stogdill 1948; Gibb 1954) has shown that a person does not become a leader solely by virtue of any particular pattern of personality traits but rather by possession of any attribute that, by virtue of its relevance to the situation and its situationally determined evaluation by other

group members, establishes a relation of leading-following.

The task. While the task must, in many respects, be regarded as an additional element of the situation, its separate significance in defining acts of leading is probably sufficient to justify separate identification. Research has not yet succeeded in establishing a taxonomy of tasks, even for small groups, that would permit exploration of the relation between task characteristics and other leadership variables. However, Carter (1953) has shown that as far as the differentiation of leaders is concerned, tasks are not discrete but may be grouped in "families." In his experiments, using the same groups, leading in intellectual tasks fell to quite different members than leading in tasks calling for the manipulation of physical objects. More recently Hemphill, during an investigation of motivation to lead, observed, "Group tasks set widely different demands or requirements for leadership. The nature of the task thus becomes an important consideration in the complex of motivational factors related to the attempt to lead. A task that repeatedly presents occasions where a decision must be made produces many attempted leadership acts" (1961, p. 212). Certainly it has been repeatedly observed that as a group moves from one task to another, the situational demands alter in such a way that different forms of participation assume leading qualities, and different members may, depending on the complex interaction of all the elements now under discussion, become influence agents and leaders.

To some degree the nature of the interaction of these elements has already been explicitly discussed or clearly implied, and little more need be said of it until particular theoretical formulations are discussed below. It will be clear, also, that any suggestion that leadership can be reduced to some specific ability or to a set of personal attributes has been abandoned (Lang 1964). The quality of leadership inheres, not in an individual, but in a role that is played within some specified social system. A satisfactory summary statement is that of Zalesnik and Moment:

Identifying leadership [or leading] as a particular kind of interaction event, rather than as a particular set of characteristics of a person, conforms to the temporal, sequential and patterned aspects of role performance. The individual who engages in leadership events becomes a sometimes leader. Thus, the group leader would be the person or persons who engaged in more leadership events than others. We would use the term *influence* as synonymous [*sic*] with leadership only when the term *intended* preceded it. Behavioral analysis describes the ways in which all members of an

interacting group influence one another; we identify as leadership only those interaction events in which *intended* influences are consummated. (1964, p. 414)

Leadership as group function

It is now common for social psychologists and sociologists, without any real or implied contradiction of the above analysis of acts of leading, to view leadership as a characteristic of a group rather than of individuals or individual acts. "Leadership is probably best conceived as a set of functions which must be carried out by the group" (Gibb 1954). As Cartwright and Zander suggest, the contemporary view of leadership, which "... stresses the characteristics of the group and the situation in which it exists, ... seeks to discover what actions are required by groups under various conditions if they are to achieve their goals or their valued states, and how different group members take part in these group actions. Leadership is viewed as the performance of those acts which help the group achieve its preferred outcomes" (1953, p. 492). As Secord and Backman (1964) then recognize, such an orientation to leadership has the clear implications (1) that acts of leading will almost inevitably be very varied indeed, depending upon the situation, the task, interpersonal evaluations, and perceptions and interactions of all of these; and (2) that acts of leading may be performed by any or all members of a group and that there is no force in the nature of the leadership relation itself, making for "focused" rather than "distributed" leadership. Furthermore, since groups have two primary "needs"—for goal achievement or achievement of "valued states" and for maintenance of the group—it is to be expected that two primary categories of acts of leading exist and that, in turn, two primary modes of leadership appear. Empirical evidence for this was offered by Bales (1953), who found in small goal-oriented discussion groups both "instrumental" and "social-emotional" leaders. Strong theoretical and empirical support for this view exists.

On this view, the provision of leadership in a group is a complex but limited aspect of the more general process of role differentiation, by which a group develops "specialists" in the performance of recurring functions. The complex of functional roles that characterizes leadership has been more fully studied than have other and probably comparable complexes—for example, that of political figure or ambassador—but it is, perhaps, questionable whether a more complete understanding of role will not supersede particular concern with leadership.

Current psychological theories

Two recent attempts (Berelson & Steiner 1964; Collins & Guetzkow 1964) to set out systematically what is known of leadership have indicated the limitation of this knowledge, and this is especially true with respect to an understanding of the process by which roles are differentiated and status or position established. Gibb (1949) observed that in newly formed groups some degree of leadership emerged within the first few minutes of interaction. The enigma of this phenomenon has still not been elucidated. While it can be confidently asserted (Collins & Guetzkow 1964) that "the greater the personal attraction of other group members to a single individual, the greater the power of that individual," there remains little understanding of the sources and nature of differential personal attraction.

Sociometry. A very large proportion of the research in leadership has made use of the sociometric method. This technique has developed greatly since the first valuable lead given by Moreno (1934) and the first sociometric study of leadership by Jennings (1943). It provides an easily accessible, relatively objective means of assessing interpersonal attitudes within a group, and by way of such linkages, it offers a means of mapping the interpersonal structure of a group [see SOCIOMETRY].

The simple but important recognition that different choice criteria could be incorporated in the sociometric question has led to very significant insights into the leadership of groups. The value of Jennings' varying the criteria from choices among group tasks to quite informal friendship choices (1947) cannot be overestimated. Role criteria in the study of leadership are now numerous, and the use of different criteria has shown that members of a group do often distinguish between those they like as friends and those they would wish to have as leaders (Hollander 1961, p. 34). The sociometric method has also demonstrated that interpersonal designation of leaders varies in any group from time to time as goals, tasks, and internal structure change.

In an attempt to explain the importance of sociometric technique to the study of leadership, Hollander (1961) has said that social interaction leads to an implicit interpersonal assessment, which the perceiver reaches by comparing task-related elements and behavior with some social standard. Parsons (1952) was responsible for a very significant advance when he indicated that persons interacting are objects to each other in an evalua-

tional process, the elements of which are cognitive (what the object is) and cathectic (what the object means in an emotional sense). Leadership is such an evaluational relationship; the cognitive component is perception of another individual's instrumentality in need satisfaction, and an emotional tone derives from the as yet not understood processes of interpersonal attraction.

The principal theories of leadership are based in some sense upon the sociometric method. Of these, mention should certainly be made of interaction theory, of Hollander's work on "idiosyncrasy credit," and of Fiedler's "contingency theory."

General interaction theory. The important aspects of interaction theory have been stated as follows (Gibb 1958). First, groups are mechanisms for achieving individual satisfactions, and conversely, persons interact with other persons for the achievement of group satisfactions. Second, role differentiation, including that complex called leadership, is part and parcel of a group's locomotion toward its goals and, thus, toward the satisfaction of needs of individual members. Third, leadership is a concept applied to the interaction of two or more persons when the evaluation of one or some of the parties to the interaction is such that he or they come to control and direct the actions of the others in the pursuit of common or compatible ends. Any group is a system of interactions. Within this system a structure emerges as a result of the development of relatively stable sets of expectations for the behavior of each member, and these expectations are an expression of the member's interaction with all other members. Thus, the particular role an individual member achieves within the group is determined both by the functional or role needs of the group in a situation and by the member's particular attributes of personality, ability, and skill, which differentiate him perceptually from others in the group. Leadership is basically a function of personality and social system in dynamic interaction. Fourth, evaluation of one party to interaction by another is itself an integration of perceptual and emotional relationships; it is a product of perception of instrumentality in need satisfaction and of emotional attachment. This form of conceptualization leads to a recognition of a complex of emotional relationships, which in turn define a variety of leadership relations. Among these may be identified (1) patriarchal leadership, in which the person upon whom the members perceive themselves to be dependent is both loved and feared; (2) tyrannical leadership, where the emotional relationship is dominated by fear; and (3) "ideal," or charismatic, leadership,

in which the interpersonal relationship is characterized by love or affection. Insofar as attention is given only to the momentary capacity of a group to mobilize its resources for a particular task, the emotional quality of the relations to a leader may be irrelevant. But if the time dimension is admitted, then the cathexis of the parties of the interaction to one another seems inevitable. It is a part of this theory, then, that even if consideration is given only to those groups in which the sources of all influence and control are within the group (i.e., if headship situations are ignored), the concept of leadership still embraces a wide variety of interactional relationships, all of which must be expected to have quite different effects in terms of group behavior. This view of social interaction gives rise to a number of hypotheses concerning leadership for which there is already some evidence in sociological observations and in the findings of psychological experimentation. Among these is the observation that, under different conditions, a leader can have varying degrees of influence on the "locomotion" of his group.

Fiedler's contingency theory. Some aspects of interaction theory have been systematically elaborated and investigated by Fiedler and his associates (Fiedler 1964). The starting point of these investigations was the widely recognized fact that while one form of leadership was associated with effective group performance in one set of circumstances, there were circumstances in which a quite contrary form seemed most effective. For example, a number of studies had shown that human-relations-oriented, considerate, or democratic leader behavior promoted high morale and productively effective behavior in a wide variety of work groups. Yet, other studies had shown task-oriented, instrumental, or authoritarian leadership to be associated with productive efficiency in experimental groups. Further examination of this research revealed that "the prediction of group performance on the basis of these leader attributes is contingent upon the specific, situational context in which the leader operates" (*ibid.*, p. 154).

Fiedler chose to measure, as predictors of leadership effectiveness, "assumed similarity between opposites" (ASo) and "esteem for the least preferred co-worker." These rather esoteric measures acquire general meaning and significance by virtue of the fact that each can be shown to bear some relation to the rather more widely acceptable variables of "task-orientation" and "consideration." Individuals who differentiate sharply between their most and least preferred co-workers (low ASo) tend to be more oriented toward the task and more

punitive. A person who sees even a poor co-worker in a relatively favorable manner (high ASo) is likely to behave in a way that shows consideration for others and promotes member satisfaction; he is also likely to be less directive.

In an early study Fiedler (1955) was able to show that the leaders' ASo scores and the performance of army and air-force crews were negatively associated for crews in which the leader sociometrically endorsed his "keyman" (e.g., the gunner on a tank-gunnery task) and were positively associated for crews in which the leader sociometrically rejected his keyman. Subsequently, Fiedler demonstrated that "The relationship between ASo scores and crew effectiveness . . . seemed to be contingent upon the sociometric choice pattern within the crew" (1964, p. 156).

Fiedler has also suggested that group situations may be described in terms of three dimensions: (1) affective leader-group relations; (2) task structure; and (3) position power. There is reason to believe that task structure and position power are not independent (1964, p. 162), and further elaboration of this model is sure to follow. The first of these dimensions reflects the extent to which the leader feels accepted by his group members. Task structure is defined in terms of four scales, developed by M. E. Shaw, which refer to the degree to which the correctness of a decision can be demonstrated, the clarity to members of the requirements of the task, the restriction of procedures by which the task may be accomplished, and the uniqueness of the "correct" solution. By "position power" is meant the extent to which the leader may dispense rewards, punishments, and sanctions, generally by virtue of authority given him by the organization within which the group operates, by tradition, or by any other formally recognized institution.

By dichotomizing each of these dimensions into high and low, Fiedler obtains eight descriptively different group-task situations. The results from many studies are then called upon to reveal the relationship between leadership style and group performance in each of these different situations. "In very favorable conditions, where the leader has power, informal backing [i.e., good leader-member relations], and a relatively well-structured task, the group is ready to be directed on how to go about its task" (*ibid.*, p. 165), as is shown by the fact that the correlations between ASo scores and group effectiveness are large and negative. In other words, the controlling, managing, and directive leaders perform best in these conditions. And under very unfavorable conditions, where leader-member relations are poor, the task is unstructured,

and the leader lacks power, the managing, controlling leadership style also proves most effective. It is in moderately favorable conditions, where the group faces an unstructured or ambiguous task or where the leader's relations with group members are tenuous, that permissive, considerate leadership is most effective. It is probably not unimportant that the situation where the leader position is weak, the task ambiguous, but the leader well liked is characterized by considerate, permissive leadership; and, alternatively, when the leader is not well liked but the task is clearly structured and his position is strong, the leadership is generally authoritarian and task oriented. This fact suggests a need for further consideration of the summary concept of favorableness of the situation. However, there is reason enough to accept Fiedler's general hypothesis that "the type of leader attitude required for effective group performance depends upon the degree to which the group situation is favorable or unfavorable to the leader" (1964, p. 164).

Fiedler and Meuwese (1963) have also shown that a leader's ability scores correlate highly with group performance only if the leader is sociometrically accepted or liked, and this finding contains the essence of the contingency theory. The fact that a person may be identified as a leader in an uncohesive group and that the correlation between his ability and group performance may be negative suggests that when the group perceives its major task to be group maintenance, the identified leader will be one who attends primarily to the performance of maintenance functions rather than to the overt task.

Hollander's idiosyncrasy credit. Within the context of an interaction theory that sees social behavior as dependent upon individual attributes, conditions of the situation, and "inputs to a dynamic system arising from their interaction," Hollander (1958) proposed a mediating construct of "idiosyncrasy credit," to explain the fact that leaders must conform to the norms of the group led and also must be a force for innovation. Basically this is made possible through the achievement of status, which is primarily a matter of the leaders' being perceived to conform to group expectancies in the areas of both high individual task performance and generalized characteristics (e.g., pleasant appearance). To the extent that a person is positively evaluated in both task competence and status external to the group, he accumulates "idiosyncrasy credit."

This represents an accumulation of positively disposed impressions residing in the perceptions of relevant others; it is defined operationally in terms of the degree

to which an individual may deviate from the common expectancies of the group. In this view, each individual within a group—disregarding size and function, for the moment—may be thought of as having a degree of group-awarded credits such as to permit idiosyncratic behavior in certain dimensions *before* group sanctions are applied. (Hollander 1958, p. 120)

Against this credit, such deviant behavior as the individual indulges in is to be seen as a debit. For any given individual, then, the extent to which he is allowed to innovate will depend upon his status. So long as he does nothing to negate the perception of himself as task competent, motivated to belong to the group, and loyal to others' expectations of him, he may enjoy sufficient credit to challenge and change prevailing social patterns in the group. But Hollander (1961) points out that "in attaining this level, the particular expectancies applicable to him will have undergone change," so there is no guarantee that it will be appropriate or possible for him to continue in innovation; in fact, the converse is more likely to obtain.

This "mediating concept" of idiosyncrasy credit is consistent with and helps to explain leader rotation in the group as task and other features of the situation alter, for as Hollander says, "the task competent follower who conforms to the common expectancies of the group at one stage may become the leader at the next stage. And, correspondingly, the leader who fails to fulfill the expectancies associated with his position of influence may lose credits among his followers and be replaced by one of them" (*ibid.*, p. 45).

Summary of current theories. The principal insistence of interaction theories in any of these forms is that the major variables in terms of which leadership might be understood are (1) the leader's personality; (2) the needs, attitudes, and problems of followers; (3) the group itself, in terms of both interpersonal structure and syntality; and (4) the situation in terms of both the physical circumstances and the group task. Further, it is clearly understood that the investigator needs to deal with the perception of each of these variables by the leader and by other group members.

Personality and leadership

In the context of interaction theories there is room for a thorough exploration of the extent to which attributes of the leader are related to the process of leadership and to group performance. Probably the earliest "explanation" of leadership phenomena was given in terms of personal qualities that, while partially modifiable and learnable, characterized the individual and established his dominance of and influence in any situation. For a

time during the late 1940s, reaction against this view was so marked that psychology seemed to some to be in danger of offering a thoroughly "situational" view of leadership phenomena. The major influences in this reaction were Gibb's report of the situational shifting of leadership in small groups (1947) and Stogdill's study of the literature of personality traits (1948), which revealed that those personality traits which were leadership traits depended upon the situation and the requirements of the group. Each of these papers, however, was interactional rather than situational in theoretical orientation. And the interactional approach has opened the way for understanding the relation between personality and leadership, while at the same time ending the quest for generalized "leadership traits."

The early tendency to lean heavily to the side of situational determinacy in this process was most effectively checked by Carter and Nixon (1949), who showed that when the emergence of leadership was studied in a carefully controlled way, through tasks which fell into three distinct "families," the leadership varied considerably from task family to task family but that within families it was relatively stable and appeared to be determined by other, probably personality, factors. In the years since 1950 many studies have provided evidence that personality factors contribute to the emergence and maintenance of leadership status. This has been especially true of those studies in which the situational variance has not been relatively great.

Representative studies. As examples, four of these studies may be mentioned.

(1) Bass (1960, p. 172) reports that in initially leaderless discussion groups extremely authoritarian personalities, as measured by the California F scale, are least likely to exhibit successful leadership behavior. On the other hand, in these groups he observed a positive correlation between successful leadership and perceptual flexibility. But probably the most telling is the finding of Klubeck and Bass (1954) that persons who do not naturally exhibit successful leadership in such groups are unable to profit from brief coaching as to how to behave as leaders, and the conclusion that these persons seem to be limited by personality and would need to undergo change, probably through major psychotherapy, before they could be freed to behave as leaders.

(2) Borgatta, Couch, and Bales have presented findings that they describe as relevant to a "great man" theory of leadership (1954). They varied the composition of three-man groups working on the same tasks and showed that individuals who scored

high on a composite of intelligence, leadership ratings by fellow participants, participation rate, and sociometric popularity in one group were also high in three subsequent group sessions, where they interacted with different persons. Those who scored highest on this composite criterion in one group did so consistently, and it was evident that "great men" selected on the basis of their first session continue to have an influence on the relatively superior performance of the groups in which they subsequently participate. However, as Hollander comments, "the task setting was essentially constant with only the participants varying across sessions" (Hollander and Julian 1964).

(3) In somewhat similar vein Cattell and Stice (1954) offered four formulas for selecting leaders on the basis of personality. They differentiated four kinds of leaders: "persistent momentary problem solvers" or technical leaders, identified in terms of the frequency with which nonparticipant observers had judged the individual to have influenced the group; salient leaders, picked by the observers as most powerfully influencing the group in at least one of the 22 situations presented; sociometric leaders, identified by choice by fellow members; and elected leaders, who were named after formal election on one or more occasions in the course of the experimental interaction.

The personality profiles of leaders were compared with those of nonleaders, and eight personality factors showed differences in the same direction for all four categories. These were *C*, emotional maturity, or ego strength; *E*, dominance; *G*, character integration, or superego strength; *H*, social adventurousness; *N*, shrewdness; *O* (negative), freedom from anxiety; *Q3*, deliberate will control; and *Q4* (negative), absence of nervous tension. Differences between leader types were that technical leaders had higher general intelligence, *B*, and elected leaders were higher in *F*, surgency. Discussing these results, the authors indicate that the relationships revealed are consistent with both technical and nontechnical thinking about leadership and the influence process. For example, the timid, withdrawn, hesitant behavior associated with a low *H* score would not be conducive to leadership in any of the categories. The anxious, worrying cautiousness in dealing with people represented by high *O* would not inspire confidence. And where conscience is considered to be the "will of the group"—a regard for superindividual values—the selection of leaders with high *G* represents a gain for the group. [See TRAITS.]

(4) Some confirmation of this finding is to be found in a study by Borg (1960). He derived four

factor scores from a variety of tests that were primarily measures of personality variables and related these to sociometric measures of six small-group roles. Twelve of his 24 correlation coefficients were significant at the .01 level. The predictor factor "assertiveness" was the most successful. A correlation of .46 was found between assertiveness scores and a composite leadership role derived from individual role measures of assertiveness, creativity, and leadership. It is interesting to observe that the predictor factor "power orientation" is consistently unassociated with this leadership composite and that a third predictor, "rigidity," dependent primarily on the California *F* scale, is consistently and significantly negatively associated with leadership, thus confirming Bass's results. As Borg himself points out (p. 115), his success in predicting especially the leadership-role scores may mean that even more can be achieved in this area if predictor instruments are further developed.

Summary of the literature. Despite the common promise of these studies and others like them, it cannot at this time be said that there is evidence for a predominant personality component in leadership. The best review of the literature in this area to date is that of Mann (1959). In the course of examining a number of relationships between the personality characteristics of the individual and the way he behaves or is perceived to behave in small groups, Mann presents a summary of the relationships between some aspects of personality and leadership, as follows.

Intelligence. After examination of 28 independent studies, the positive association of intelligence and leadership in small groups seems to be beyond doubt, although the median correlation is only .25; no reported coefficient exceeded .50; and just half of the results examined failed to establish the significance of this trend.

Adjustment. The association of personal adjustment and leadership was found in 22 studies. Again the over-all trend is clearly positive, with a median correlation of approximately .15 and no single correlation coefficient greater than .53.

Extraversion-introversion. Twenty-two different studies have suggested a median correlation between extraversion and leadership of .15, and the highest correlation reported is .42. Despite some difficulty in ensuring the real similarity of scales of similar title, there is evidence for the conclusion that "those individuals who tend to be selected as leaders are more sociable and outgoing."

Dominance. On the evidence of 12 studies, dominance, as measured by personality scales, is positively associated with leadership, having a

median correlation around .20 and a highest reported correlation of .42. "Although the trend is not very strong, these data suggest that dominant or ascendant individuals have a greater chance of being designated leader."

Conservatism. Seventeen studies reveal that in general there is a negative association between conservatism and leadership. Mann found that the California *F* scale had been used ten times in the prediction of leadership and that on each occasion authoritarian persons had been rated lower on leadership.

Interpersonal sensitivity. The measurement of interpersonal sensitivity, or empathic ability, has been subject to much attention. Some caution is needed in attempting to summarize the 15 studies relating it to leadership, and Mann duly qualifies his summary judgment that "there appears to be a low but clearly positive relationship between interpersonal sensitivity and leadership."

Evaluation and other techniques. A further and even more important qualification of these results is made by Mann in pointing out that leadership is variously determined by one of three popular techniques: peer ratings, criterion measures, and observer ratings. The relationship of some of the above personality variables differs when these different measuring techniques are used for leadership. While the relationship between intelligence and leadership is independent of the technique of identifying leadership, that between adjustment and leadership is more closely associated with peer ratings or informal leadership than with either of the other forms; extraversion is more likely to characterize formal leaders determined by criterion measures. Further, Mann observes that "extraverted individuals are no more likely than introverted individuals to be rated as informal leaders by their peers." To a large extent the significance of this observation by Mann, based upon a careful scrutiny of the literature, is that it confirms, in principle at least, the Cattell and Stice proposal of different regressions of personality measures upon different measures of leadership.

The evidence of research to date is clear in demanding that future research attempting to relate personality variables to the exercise of influence in groups must make use of more refined concepts than that of leadership, and close attention must be given to the techniques used to assess both personality and influence relationships.

Leadership in the enduring group

Implicit in the recognition that leadership is situation contingent is the understanding that

leader behavior varies with such group factors as organization structure and pattern of communication. Probably the most prominent determinant of variation in these structural respects is the duration of the group. Much of the research in the psychology of leadership has employed newly formed groups of short duration, while a great many of the groups with which social science generally concerns itself are those that endure for a considerable period and either have or achieve a significant history. Sherif and Sherif (1948) have done much to establish the fact that enduring groups develop an organization and structure that becomes a considerable determinant of group-related behavior; and, indeed, they discuss leadership within the context of such structures. Secord and Backman (1964) properly indicate that "in groups that have functioned long enough to develop stable structures and a certain routine much of the stability in leader personnel can be explained" in terms other than those of personality-situation interaction. [See GROUPS, *article on* GROUP FORMATION.]

In enduring groups it is patent that formal office structure usually remains relatively stable, continuing from one situation to another throughout a formal term. This cannot always be regarded as continuing leadership. Primarily because of the complex values of stable structure and because there is a culture-carried expectation that offices will be filled for predetermined periods, groups maintain a status structure even if it no longer corresponds to functional demands. One result of this culture-carried expectation of persisting organization is that the nature or emotional-relational quality of leadership will change. In the early stages of group development persons emerge as organizational leaders by virtue of their control over problem-related resources or they emerge as positively cathected leaders by virtue of both their command of resources and the readiness members show to relate themselves emotionally to others on the basis of first impressions (Gibb 1949; 1958). As interaction persists, structure is stabilized for a variety of reasons. With time, the early congruence of the cognitive relation to the person controlling resources and the positive cathexis of that same person is reduced. When stability of structure, then, is formalized so that offices are held for a stated time without reference to contemporary contributory strength in problem solving, leadership becomes less functional and the officeholder is supported by structural rigidity. His leadership may now be said to have become headship, and the dynamics of the group will almost certainly have become complicated by the emergence of new leaders,

thrown up by the complex of forces, which now includes, of course, the behavior of the formal officeholders. The officeholders strive to maintain the satisfactions of office, whether these be simply of status or more complex, and in doing so their behavior becomes more coercive. Frequently this implies the establishment of power cliques or bureaucracies. Under such conditions the emotional quality of relations to the leader or head becomes less positive and the nature of the influence has changed. [See BUREAUCRACY.]

However, in other, simpler, and more direct ways, too, the time dimension, or history, has been seen to affect leadership. Klein (1956) has suggested that communication structure may become habitual and independent of the problem to be solved. A structure that has been successful repeatedly because problems have been similar will, she suggests, be persisted in even when problems become dissimilar, because of a preference for orderliness and routine. Bass (1960) has shown that the perceived status an individual brings into a group by virtue of past interaction in the group or in another, mutually known group directly affects his willingness to make attempts to lead and the success of such attempts. As Secord and Backman (1964) observe, the communication and status structures mutually reinforce each other and together constitute strong forces determining leadership. One's position in group structure, whether in the communication net or in the mutually perceived status hierarchy, greatly affects his opportunities and abilities to exercise influence. Obviously communication centrality and status position are not independent. Hopkins (1964) adduces considerable evidence for the proposition that "for any member of a small group, the higher his rank, the greater his influence."

Two final points of some significance have also been made by Secord and Backman (1964). First, once having achieved success in leadership, and through it having attained centrality and status, which in turn tend to establish their leadership, these leaders have the best opportunity to develop leadership skills, which further accentuate their positive evaluation. Second, because of the community value placed upon status and leadership directly, established leaders are highly motivated to maintain their roles, while reciprocally, their success spells satisfaction for their followers, whose involvement may be correspondingly reduced.

II

SOCIOLOGICAL ASPECTS

To most sociological writers leadership is the exercise of power or influence in social collectivities, such as groups, organizations, communities, or nations. This power may be addressed to any or all of three very general and related functions: establishing the goals, purposes, or objectives of the collectivity; creating the structures through which the purposes of the collectivity are fulfilled; and maintaining or enhancing these structures. Sociological studies have emphasized the last function, in part because it seems more amenable to empirical investigation, particularly in bureaucratic settings, where much of the research on leadership is conducted. This emphasis has implied an interest in the role of leadership in maintaining the integrity and viability of the collectivity against threats, both internal and external, in maintaining collective order and unity, in minimizing dissension and conflict, and in motivating members and fostering their acceptance of the collectivity, of its goals, and of leadership itself. Thus, most theories of leadership are conservative in that they are addressed to the maintenance of social systems rather than to their change. Although this is not an exclusive emphasis, it is consistent with a major concern in contemporary sociology with the problems of social order and stability.

The exercise of power or influence implies "making things happen" through others. Leaders may engage in a number of activities in furthering this purpose. They may coordinate, control, direct, guide, or mobilize the efforts of others. A recent focus on the leaders' role in motivating members implies that they may counsel, support, help, persuade, or elicit the participation of others in some degree of

goal setting. Leaders may also cajole, manipulate, entice, reward, coerce, or harangue, although some writers exclude some of these activities from the definition of leadership. "Strictly speaking," according to Schmidt (1933, p. 282), "the relation of leadership arises only where a group follows an individual from free choice and not under command or coercion and, secondly, not in response to blind drives but on positive and more or less rational grounds."

Many of the above activities of leaders are concerned with the details of interpersonal relations. Leaders may also wield power in representing the collectivity in its external relations. Or they may make decisions and formulate policies on a broad scale without becoming directly involved in the details of their execution. Seznick (1957) applies the term "institutional statesman" to those organization leaders who look beyond questions of routine administration and productive efficiency to the broader philosophic implications of the collectivity and its role in the larger society. Organization statesmen assume responsibility for defining policy values and for developing a plan of organization that embodies these values. Similarly, Harbison and Myers (1959) employ the term "organization builders" for those leaders who devote themselves to creating organizations. These leaders are concerned as much with innovation as with collective stability. Leaders in developing nations, in particular, are concerned with change, with defining new collective goals and creating structures appropriate to these goals. Many of these leaders must also undertake the difficult task of establishing new social values in the context of traditional philosophies (Fourastié & Vimont 1956, p. 57).

Leadership defines, initiates, and maintains social structure. The social system is, so to speak, "programmed" through leadership. Understanding leadership, then, should be a simple and parsimonious approach to understanding the larger social system. Leadership can have consequences for the lives and welfare of large numbers of people, and, therefore, those who are concerned with the practical consequences of human actions must be concerned with leadership.

Important social values are also frequently associated with leadership conceptions, and attempts are made to legitimate social systems in terms of particular theories or ideologies of leadership. The drama of leadership can be seen in its consequences and in the behavior of some well-known leaders. History is personalized and dramatized through stories of leadership, and the names of famous or infamous leaders elicit strong feeling. But the

drama associated with leadership, together with its apparent theoretical and practical import, gives it an appeal that may sometimes be deceptive. The "great man theory," according to which outstanding leaders determine the course of history, is one expression of this appeal. Models of ruling elites, which explain whole social systems in terms of power concentrated in the hands of relatively small and exclusive leadership groups, are similarly appealing in their simplicity and drama. "The whole history of civilized mankind," according to Mosca, "comes down to a conflict between the tendency of dominant elements to monopolize political power and transmit possession of it by inheritance . . ." ([1896] 1939, p. 65). The United States, according to Mills's more contemporary analysis (1956), is dominated by a "power elite" that is in command of the major organizations of society.

Sociological treatments of leadership have leaned heavily on conceptions applying to elites, to autocratic systems, and to rigid class or caste societies. Almost all of the literature on leadership, according to Bell, stems from the works of Aristotle and Machiavelli and is committed to "the image of the mindless masses and the image of the strong-willed leader" (1950, p. 396). Classical models of bureaucracy share with these elite conceptions an authoritarian bias in their emphasis on the exclusive prerogative of leaders to command and the unquestioning obligation of subordinates to obey (Weber 1922a).

According to Michels (1911), leadership and democracy are incompatible. Leadership inevitably becomes oligarchic, even in political organizations that start democratically and are committed to a democratic ideology. Leaders themselves are incapable of deflecting this historic process; democratic and idealistic leaders succumb eventually to the corruption inherent in power. Michels cites a number of arguments in support of the tendency toward oligarchy in social systems. First, the masses, through incompetence and apathy, cannot and do not want to participate actively in the political process; they prefer to be led. Second, democracy is structurally impossible in large and complex social systems; there is no way of arranging the systems so that the views of the many individual members can be heard and taken into account. The impracticality of democracy is especially apparent in organizations or nations undergoing conflict with others. Especially during periods of crisis, organizations need firm leadership and precise adherence to orders. Finally, the tendency toward oligarchy results from the character of leaders themselves and of the role they must play. Because

of their cultural and educational superiority over the masses, leaders form a distinct elite. The status, perquisites, and privileges associated with the leadership role serve further to separate the leaders from the masses. In labor unions and socialist parties, for example, the life of the leaders becomes that of the petty bourgeois. Leaders therefore develop a vested interest in their positions, which they must protect. Furthermore, a personal lust for power, which is characteristic of leaders, intensifies their efforts to enhance their power, and leaders will resort to ulterior devices toward this end. In 'democratic' parties leaders will employ emotional and demagogic appeals to manipulate the gullible masses. They will control the party press, using it to describe themselves in the most favorable light, while deriding their opposition within the party. They will exploit their special information and knowledge of the organization to outmaneuver opponents. And if, despite these tactics, the leaders should be overthrown, the new officeholders in their turn will undergo the inevitable "transformation which renders them in every respect similar to the dethroned tyrants. . . . The revolutionaries of today become the reactionaries of tomorrow" (Michels 1911, p. 195 in 1962 paperback edition).

Changes in the character of leadership

Many of the classical conceptions of leadership, including those in Weber's work on bureaucracies and in Michels' on political organizations, have proven valuable in analyses of contemporary social systems. Nonetheless, the changing character of societies over the years, and of leadership itself, has made apparent some of the limitations of these older conceptions. The emphasis in contemporary sociology on quantitative research has also contributed to changes in interpretations of the leadership process because of the need to develop conceptions that are operationally feasible as well as theoretically meaningful. At the same time, research findings themselves have led to reinterpretations of older conceptions.

The increasing numbers and complexity of organizations in modern industrial societies require large numbers of persons with high levels of technical and administrative expertise to play leadership roles. The demand for expert leaders reduces the suitability of those recruited on the basis of social status or of family connections. Achievement thus replaces ascription as the basis for placing leaders, and their recruitment spreads to all strata of society. Similarly, political criteria prevalent as the basis of recruitment during early stages in newly independent countries and in revolutionary

societies become less important in highly industrialized societies. Training centers for leaders are established in universities, business schools, and training institutes, and the possibility for careers in industrial leadership are opened to large numbers of persons. Management becomes professionalized. While these developments are most apparent in business and industrial organizations and in some agencies of government, they are also occurring in other organizations, including military establishments and labor unions (see Kerr et al. 1960).

Most of these changes imply a rationalization of leadership in organizations that is consistent with Weber's (1922a) model of bureaucratic leadership. However, further changes in the way leaders exercise control are likely to accompany this rationalization, and these represent a divergence from the classical bureaucratic model. For example, leaders may rely on discussion and persuasion rather than exclusively on command. Attempts may be made to elicit cooperation, sometimes by having organization members participate in the making of decisions that affect them in the work place. The rising level of education of the work force contributes to this trend. Furthermore, professional managers are more inclined than their predecessors to consider the results of social research, which have supported the growth of "human relations" approaches to leadership in organizations. At the same time, political developments, particularly in some European countries, have led to the introduction of schemes for co-management and of workers' councils, with varying degrees of success (Emery & Thorsrud 1964; Meister 1964; Sturmthal 1964). These developments may not be fully consolidated in any contemporary society, but at least incipient support can be found in many organizations for less autocratic approaches to leadership than those that were customary in the past. A survey in 14 industrialized and developing nations, for example, shows that managers overwhelmingly subscribe at least to the idea of participation in decision making, although they express skepticism about workers' capacities to assume the responsibilities consonant with democratic leadership (Haire et al. 1963).

Taken together, these developments imply the growth—actual in some places, potential in others—of new types of leadership in addition to those prevalent in the past. Partly as a consequence of this trend and of developments in research, sociological conceptions have been broadened. This can be observed in a number of related issues.

Leader power. Many of the limitations of traditional leadership conceptions stem from assump-

tions about the social context within which leadership operates and about the character of power, which is the essence of leadership. One such assumption is that the context is one of conflict, in which the relative power of leaders and others is at stake. It is further assumed that the total amount of power in a social system is a fixed quantity and that leaders and followers are engaged in a "zero-sum game"—that is, an increase in the power of one party must be accompanied by a corresponding decrease in the power of the other. Contemporary social scientists are more inclined than their predecessors to question the generality of these assumptions (Likert 1961; Parsons 1963; Tannenbaum 1966, pp. 95–100). The total amount of power in a relational system may grow, and leaders and followers may therefore enhance their power jointly. Total power may also decline, and all groups within the system may suffer corresponding decreases.

Another view common to traditional analyses argues that the leadership process is unilateral: one either leads or is led, is strong or is weak, controls or is controlled. Georg Simmel, in spite of his general adherence to the traditional conflict view of leadership, noted a more subtle interaction underlying the appearance of "pure superiority" on the part of the leader and the "purely passive being led" of the follower: "All leaders are also led; in innumerable cases the master is the slave of his slaves" ([1902–1917] 1950, p. 185; contrast *ibid.*, p. 193). Contemporary analyses of leadership are more likely than earlier ones to consider relationships of mutual as well as unilateral power, of followers influencing leaders as well as vice versa.

An accompanying change has taken place in analyses of the bases of leaders' power. Coercion has played a prominent role in traditional analyses, consistent with the presumed conflict between leaders and followers. According to the traditional view, leaders are obeyed out of fear of punishment or out of hope for reward. Machiavelli, for example, advised his prince concerning the proper balancing of injuries and benefits to subjects. The leader who finds it necessary to commit injuries should do so quickly in order to minimize resentment. On the other hand, he should dispense rewards in small doses over time so that their effects will be enjoyed longer.

Weber, however, argued that the stability of social systems depends on acceptance by followers of the right of leaders to exercise control. This implied *legitimate* authority; and Weber (1922b) defined three types, all of which share a prominent position in sociological analyses of leadership. The

first type is *charismatic authority*, according to which leaders are thought to be endowed with extraordinary, sometimes magical powers. Charisma on the part of a leader elicits obedience out of awe. It is illustrated in its pure form by the prophet, the warrior hero, and the great demagogue. Second, *traditional authority* appertains to those who possess the right to rule by virtue of birth or class. The traditional leader is obeyed because he or members of his class or family have *always* been followed. Its pure type is illustrated by certain patriarchs, monarchs, and feudal lords. The third type, *legal authority*, applies to those who hold leadership positions because of demonstrated technical competence. Legal authorities act impersonally, as instruments of the law, and they are obeyed impersonally out of a sense of duty to the law. Leadership in the ideal-type bureaucracy is based exclusively on legal authority.

The character of leadership envisioned within Weber's framework is still consistent with many of the traditional analyses; his leaders are prophets, warriors, demagogues, patriarchs, lords, and bureaucrats. More recent analyses have stressed bases of power in addition to those outlined by Weber.

Simon, for example, points to the importance of *social approval*. Approval and disapproval represent forms of reward and punishment, but they deserve special consideration, since they are frequently dispensed not only by the designated leader but by others as well (1957, pp. 105–106). Thus, a subordinate may obey a leader not so much because of the rewards and punishments meted out by the leader as because of the approval and disapproval given by the subordinate's own peers. *Confidence* may represent a further basis for acceptance of leaders' authority (*ibid.*, p. 106): a subordinate may trust the judgment, and therefore accept the authority, of a leader in areas where the leader has great technical competence. French and Raven (1959) make a further distinction between influence of a leader based on confidence by subordinates in the leader's expert knowledge, on the one hand, and "informational influence" based on acceptance by subordinates of the logic of the arguments which the leader offers, on the other. An expert leader, then, may be followed not simply because he is an acknowledged authority but because his decisions, being based on expertise, are manifestly logical, appropriate, and convincing; that is, subordinates are persuaded that the decisions are correct. This view is related to human relations approaches, which stress control by facts as opposed to control by men. Such "fact control" relies on *understanding*, and it is illustrated by the

participative leader who influences subordinates by helping them understand the facts of a situation so that they may jointly arrive at a course of action consistent with their own interests and that of the collectivity. Some of these conceptions represent radical departures from many traditional ones, assuming as they do an overriding community of interests between leaders and followers.

Leaders and followers. The term "leader" has traditionally implied a person clearly distinguished from others in power, status, visibility, and in any of a number of character traits, such as decisiveness, courage, integrity, and intelligence. However, contemporary changes in assumptions, in the direction of recognizing both mutual influence between leaders and followers and the possibility of increasing total power, have led to some lack of clarity in the lines of demarcation between leaders and others. Human relations and participative approaches to leadership, which de-emphasize status and stress the community of interests among all members of the collectivity, also blur the conceptual distinction between leaders and followers. The results of research have added to this ambiguity.

First, little evidence has been found for the existence of universal character traits that define the essential and distinguishing qualities of leadership. This has strengthened the position of those "situationalists" who argue that the relevance of a trait will depend on the specific situation in which leadership occurs. Furthermore, while leaders in similar situations may share *some* relevant characteristics, they are also very likely to differ on others, so that their total personalities will certainly differ. Research also suggests that traits (e.g., intelligence) that may suit an individual to some leadership roles are likely to be distributed continuously in a population rather than dichotomously. Nor is there any basis for assuming that the traits pertinent to many leadership roles are so rare that large numbers of persons differing widely in total personalities would be ineligible for leadership positions.

As a group, therefore, leaders need not be alike, nor need they be distinguished sharply from followers. These conclusions are consistent, in some of their implications, with the changing character of leadership itself, in which the broad recruitment and trainability of leaders is stressed. Leadership abilities need not be an exclusive possession of narrowly defined types or classes of individuals. Many persons, given proper training, can perform a wide range of leadership functions.

Research has had a further effect on the conceptual distinction between leaders and followers. In terms of the operational criteria used to define and

measure leadership behavior, many presumed followers are found to act in some degree like leaders and vice versa. Furthermore, the *same* individual may manifest different degrees of leadership behavior. He may be a leader at one point in time, not at another. He may be a leader relative to certain areas of collective action, not others. Leadership, then, is best understood as a matter of degree; it may be distributed in varying degrees throughout a social system. These interpretations call attention to leadership as a social function rather than simply as a property of an individual. While persons who perform leadership functions must have appropriate skills and qualities of character if they are to perform well, the *distribution* of leadership in collectivities and the variety of situations in which leadership occurs suggest some variety in the types of persons who can fulfill leadership functions [see *GROUPS*, article on *ROLE STRUCTURE*].

The concept of leadership should be understood as encompassing a wide range of activities. It applies to the running of small groups and the governing of nations. It may concern the relatively diffuse process of influence in establishing norms of style or opinion—or it may involve specific orders in a chain of command. It includes supervision and statesmanship, routine administration and organization building. Interpretations of leadership as a sociological concept have changed over the years. The total effort of sociologists can be seen as an attempt to develop conceptions that apply to a variety of social systems, including those that prevailed in the past as well as those now emerging. The need for more general conceptions is also felt as a need to understand leadership within the widely differing social and political contexts that exist in the modern world.

BIBLIOGRAPHY

For definitions, reviews, and discussions of leadership see Schmidt 1933; Gouldner 1950; Gibb 1954; Rouček 1947. Bass 1960 provides a thorough review of laboratory research as well as the research on leadership in organizations. For a classic expression of the great man theory of leadership, see Carlyle 1841. Plekhanov 1898 offers a critique of the great man view. Critiques of elite theories can be found in Dahl 1958 and in Harbison & Myers 1959, which also presents a detailed discussion of changes in industrial management and in social and political leader-

ship brought about by industrialization. Bendix 1956 provides a review of traditional and more recent leadership ideologies as applied to industrial management in western and eastern Europe and the United States. Dahrendorf 1957 and Parsons 1963 discuss the issue of power in collectivities as a zero-sum game. Leadership under conditions of mutual influence and increasing total power (non-zero-sum) is illustrated by the principles of "co-optation" Selznick 1949; "participative management" March & Simon 1958; "interaction influence system" Likert 1961; "organic" as opposed to "mechanistic" organization Burns & Stalker 1961; and by the concept of high "total control" Tannenbaum & Kahn 1957 and Tannenbaum 1966. The trait theory of leadership remains controversial. Rainio 1955, in a review of some of the American and European literature, lists 99 traits that are presumed by various authors to represent the essential qualities of leadership. See Bogardus 1934 and Urwick 1957 for illustrations of the trait approach; see Bavelas 1960 for a critique.

III POLITICAL ASPECTS

By the middle of the twentieth century, in new nations and old, social and economic changes had imposed on all regimes new demands that resulted in greatly augmenting the power of executive leaders. Prime ministers and presidents, not legislators, were asked to supply the innovation and integration that these situations demanded.

In democratic regimes the executive is no longer merely an arm of government but has become the organizing center of the political system itself. A parliamentary regime in France was transformed into Charles de Gaulle's executive rule. West German politics were stabilized by Konrad Adenauer's shrewd balancing. British politics, in the opinion of some, has been transformed from cabinet government to prime-ministerial government. In the United States the president and the presidential corps have become the fulcrum of politics.

In many emerging nations, democratic forms of government, which have only recently been instituted, are precariously sustained by dramatic executive leaders who rule by mass appeal and the exercise of broad political powers. Fragile identifications with the new national entities are nurtured by mass loyalty to the leader. By personifying the new national values and giving a relentless drive to development, executive leaders energize the mobilized advance of these societies.

Twentieth-century social thought has expressed the paradox that leadership is a solution to the problems of both excessive and insufficient political power. Strong executive leadership was offered as a solution to two general and characteristic maladies of political systems. First, the ideologists of authoritarian movements and regimes proposed strong leadership as a substitute for atrophied traditional primary-group identifications—community, church, family, etc. The breakdown of traditional norm-fostering groups, they argued, leaves society open to conflicts that could be overcome or avoided by strong identification with po-

litical leaders. This was a seminal explanation of fascist and communist movements in Western industrial systems and of nationalist movements in preindustrial, developing countries.

Another ideological premise was that only effective leadership can furnish integrative direction and action as a cure for the stalemated pluralism endemic to Western democratic systems. Competing interests wear down consensus and paralyze national decision making. The pathology of political pluralism, the argument ran, is *immobilism*. Under such conditions, only strong executive leadership can furnish decisive national purpose. The most striking recent illustration has been the ideological justification surrounding the presidency of de Gaulle in France. Weaker but nonetheless insistent echoes of this ideology reverberate in the justifications for increasing the powers of other democratic chief executives—the American president, the British prime minister, and the German chancellor.

This integrative function of leadership is fulfilled by two political role types. One is the national hero—the chief executive as personification and representative of the “general will” or “higher interest” of the nation. De Gaulle and the leaders of many emerging nations exemplify this type. Like Rousseau's legislator, such populist figures stand above politics and particular interests. The second is the executive as political broker or artful synthesizer, exemplified by Franklin D. Roosevelt, that is, the expert manager of interests and builder of coalitions.

These two roles are distinct but not mutually exclusive. Each has its relevance in different political systems at particular times. The “general will” spokesman is called into power when national consensus becomes problematical; the “broker” comes to power when a viable consensus exists, unthreatened by polarizing and uncompromisable conflicts—when the management of interest conflicts is the compelling need. To some extent every chief executive must fulfill both roles.

Leadership theory and political executives

The principal functions of chief executives may vary, but all are responses to leadership demands and expectations by the led. Hence, understanding of executive behavior depends in large measure on understanding the phenomenon called leadership.

Historically, the concept of leadership was derived from leadership in a religious sectarian setting or in groups of primary relationships. Sectarian followings inspired by prophetic figures

have been at the genesis of many religious movements. Moses, Muhammad, Jesus, Calvin, and many others are illustrative. The solitary, dramatic personality who mobilized and inspired masses to new goals and methods of religious salvation became an important prototype of leadership.

This conceptual view was reinforced by research on historical and primitive governmental institutions, e.g., tribal chiefs and leaders of small city-states, vested with absolute authority. Such studies also contributed the notion of status and hierarchy to the concept of leadership. Power was vested in the *status*, as well as in the person, of a ruler. The personalization of leadership was thus further reinforced.

By the twentieth century several intellectual trends had already effected a change in this conception of leadership. First, the democratic revolution of the eighteenth and nineteenth centuries depersonalized the concept of authority. Power, prescribed and defined in constitutions and law, was vested in the *office*, not the person. The scope and jurisdiction of public officials were given limits in law, so that arbitrary power could be prevented. Rules about leadership succession were specified, to check seizures of power by violence. Office set boundaries to personal influence, and the institutionalization of the executive was firmly implanted.

Second, the positivistic influence of the social sciences drastically modified the concept of political leadership. The traditional "hero" disappeared in the face of new views of psychology. The prevailing instinct-and-trait psychology gave way before the critiques of Mead, Cooley, Dewey, and others and their conceptions of a variable human behavior molded by social interaction. Leadership came to be viewed, not as a set of fixed traits and attributes, biologically peculiar to some individuals, but as a role that satisfies mutual expectations of leaders and followers.

Building on this new, interactional emphasis, research in the social sciences (invigorated by experimental emphasis) added increasing sophistication to the concept of leadership. Situational and group components were strongly emphasized. The leadership role was found to vary with situations. Leaders are always, covertly or overtly, "preselected" by their supporters according to the situational needs of the group. Leadership is a nexus of need fulfillments that binds situational demands and group membership. Thus, during crisis situations groups are likely to select leaders who diagnose problems quickly and act decisively. During less critical periods, leaders who can main-

tain cohesion and regularity of group performance may be preferred.

Another factor was given emphasis: group goals. Leadership is a differentiated role that enables group purposes to be realized. Where a group is task oriented, leadership integrates the members so that individual needs and group performance can be enhanced. Groups with other purposes choose leaders of another type.

Much insight on leadership is derived from experimentation with and observation of small groups. However, problems arise when such "micro" research is elevated to the "macro" level of many political science concerns. Can insights about leadership that are derived from small-group situations be extrapolated to large units or systems as a whole? Certainly, small-group situations are not replications of nation-state political systems. The danger of such extrapolations has been widely recognized, but general agreement exists that small-group leadership can provide suggestive simulations and simplifications for studying larger units. [See GROUPS.]

Characteristics of executive leadership. Analysis of the leadership of chief executives or of national political executives poses special problems to the social science analyst. In contrast to leadership in small-group situations, executive leadership is distinguishable by at least the following: (1) it is leadership at a distance; (2) it has a multirole character; (3) it has a corporate character; (4) it functions in an institutional framework.

If leadership is an interactional relationship, then the relationship between the chief executive of a modern state and his public supporters has the unique character of being leadership at a distance, where neither leader nor follower has *direct* impact upon the other. The relationship is mediated by mass communications, organized groups, and individuals. The leader is linked to his supporters by people who play many roles on various levels of the political system. The relationship between followers and leader is at some remove and therefore indirect. When Harry Truman ordered an atomic bomb dropped on Hiroshima, he could not see the consequences of his decision on the victims nor could he receive the immediate feedback.

Executive behavior is multirole conduct, fulfilling a variety of expectations that flow from various clienteles—from those immediately around the executive, from political parties and political associations, from the various bureaucracies and their political networks, and from the general

public. One of the major tasks facing a chief executive is maintaining these different roles in balance. Role expectations are met by various techniques of reconciliation, e.g., by assigning priorities to various roles, minimizing some and stressing others; by insulating incompatible ones from each other; by delegating some and reserving others. What we have come to call the "style" of leadership has its referents in patterns of role management.

Modern executive leadership is an organizational process. The American presidency, the French presidency, and the British office of prime minister are corporate entities, consisting of a sizable staff. In such an organizational context, "leadership" may be attributed to an individual but it is in reality a collective product of organizational activity. It is generically distinct from the leader-led relationships of small-scale situations.

In its organizational context, executive leadership presents a complex face. The chief executive today has become a symbolic individual, whose many roles are collectively filled by several men. If the chief executive is expected to make programmatic statements in some policy area, then corps of experts and speech writers are grouped to produce such a statement. Before the executive makes decisions, various people, playing specific and general roles, define the situation and its alternatives for him. His manifold duties are all largely carried out *in his name by others*. Executive leadership has become institutionalized.

This inner leadership group or staff may be called the executive elite. All executives are dependent upon such a collective formation to perform their tasks. In the United States, for example, it is composed of several groups, some formally organized and some informal. Included among these are the White House staff, the Bureau of the Budget, the Council of Economic Advisors, the National Security Council, and many specialists and *ad hoc* committees. Various presidents have organized and used these cadres in different ways, depending on their interpretations of their roles. In Great Britain, Churchill instituted the so-called Statistical Section, the prime minister's brain trust. Numerous cabinet committees have been established, as well as staff agencies to coordinate the work of the prime minister and the cabinet.

Finally, executive leadership is a process that operates within an institutional framework. At any given time there are prescribed norms that bound and define the scope of authority and the channels of its exercise. These limits are fairly elastic. The

chief executive, by the style of his operation, stretches or contracts the boundaries of the position. When the boundaries are exceeded, crisis exigency must justify the practice. At other times, executive boundary aggrandizement is resisted and can be accomplished only by skillful political bargaining on the part of the chief executive.

Because of its corporate and institutional character, the office itself is not wholly dependent upon its occupant. A cumulative heritage of decision and expectation has established precedents that make much of an executive's conduct predictable. This cumulative institutionalization of the office supplies continuity to all executive positions. Cases of sudden death or disability of the chief executive have demonstrated that the office functions in the absence of its principal. Such situations dramatically illustrate the fact that, while in normal times the corporate entity called executive leadership is sensitive to situational demands, it also has a degree of trained "insensitivity" and routine which gives it stability and continuity.

Some doubts have been raised as to whether this cumulative institutionalization might jeopardize executive capacity for decision. The growth in personal agents and *ad hoc* groups testifies to the vigor with which executives strive to prevent overencumbrance by bureaucratization.

Legitimations of executive behavior

The structure of executive leadership is complex because of its multirole, organizational, and institutional context. This complex structure relies on diverse legitimations for support. [See LEGITIMACY.] Generally, the democratic chief executive is legitimated by his identification with the central values of his social system, both nonpolitical and political; by the manner in which he is recruited; by the symbolic and effective representation he bestows; and by his decision-making performance.

Societal and political values. Chief executives are legitimated by their identification with the most pervasive goals in society—that is, their embodiment of a national consensus. Thus, Adenauer personified rebirth of the German republic, in keeping with a pre-Nazi, republican past. De Gaulle was in part legitimized by his absorption with a romantic restoration of French glory and power. The sacred values of the system, those beyond dispute, must be expressed and epitomized by the chief executive.

The political goals of the executive must conform to the traditional political value system. Even the most innovating and precedent-shattering

presidents and prime ministers affirm their adherence to the traditional substantive political values of the system. In Western democracies the chief executives must also affirm their adherence to procedural values—popular consent, parliamentary representation, majority rule, and civil liberties. They must profess respect for, and act in accordance with, the traditional continuities of the system.

Recruitment. The manner in which executives are recruited and elected provides an important basis of their legitimation. In normal times their nomination and election reflect their acceptability to party elites and the general public. Recruitment methods chart career paths and provide a test of the skills regarded as requisite. Most American presidents have been middle-class professionals, usually chosen from the echelon of governors of the leading states. The path to the post of British prime minister has been open to those of a certain social status, educational background, and parliamentary and cabinet career. The path of political mobility reaffirms the central values of the system. [See POLITICAL RECRUITMENT AND CAREERS.]

In the United States, as an expression of American egalitarian beliefs, it was expected that a president should rise from humble origins. He would thus embody the American ideal of success by achievement and competence rather than because of family status. The same ethos influences presidential appointments to staff and cabinet.

During periods of crisis or stalemate, recruitment patterns are disrupted. Then chief executives may be co-opted from outside conventional grooves and without the usual political experience, as was the case with de Gaulle in France. Such deviations from established patterns are legitimated by crisis needs and have themselves become a "tradition."

Symbolic and effective representation. The chief executive must represent or appear to represent the public at large and its various component segments. He does this in several ways. A common method is the appointment of spokesmen of various groups to his cabinet and to leading offices. Another method gives group representation through an executive staff accessible to various interests.

Another facet of representation by a chief executive may be called "apparent" representation. This is expressed in the many subtle forms of symbolic recognition bestowed by the chief executive upon various groups in the population. When the prime minister of England sends messages to conventions and when the president of the United States greets group delegations of many kinds, they are conferring status and symbolic recognition.

Both apparent and effective representation by

the executive are important, because there are general expectations of access and status. The chief executive's audience and clientele must be (at least in a symbolic way) *all* the consensual groups in the system. [See REPRESENTATION.]

Decision making. Finally, the chief executive is legitimated by his decision-making performance. Despite overarching "sacred" authority, the effective influence of the chief executive is tested by his capacity to carry out certain policies. The failure or success of his leadership depends upon his effectiveness in knitting together political influence so that it responds to functional demands of the system. It is to this decision-making aspect of executive leadership that the greatest analytical attention has been devoted in recent years. [See DECISION MAKING, article on POLITICAL ASPECTS.]

Dilemmas of legitimation. The more chief executives are expected to perform, the greater the contradictory pressures which confront them. Crises of legitimation arise when acute tensions develop between several levels of legitimation. A political position that is legitimized by sacred values for what it "is" encounters dilemmas when it is called upon to "do." Despite the secularizing separation between politics and religion, overmoralization of politics makes political tasks delicate. The holders of public office carry the burden of excessive expectations of rectitude and exemplary conduct, yet they are also expected to behave expeditiously in order to be responsive to public demands.

Another dilemma that confronts chief executives arises from the gap between the executive elite and the public. They must bridge the social and political distance between their special knowledge and the need for responsiveness by the public. The executives must wear different faces at different stages of the policy-making process: when they formulate policies; when they settle for those that are acceptable; and when they implement the accepted ones.

Another dilemma arises out of the conflict between the expectations of the status or position and the political capabilities to fulfill such expectations. Often the public simplifies and exaggerates expectations of executive action. Yet the modern executive in democratic societies is limited by law, administrative organization, group resistances, and the climate of opinion from fulfilling such expectations. Status and influence are not equivalents, and many chief executives fail because their power is not commensurate with their status.

Efforts to resolve these dilemmas of legitimation generate new roles for members of the executive

elite. Executives need "buffers" and "catalysts," expert bargainers whose freewheeling, unofficial conduct, is screened off from usual scrutiny. The appearance of rectitude can be maintained as long as the occupational "dirty work" is performed by executive agents.

Dilemmas are also resolved by the executive's efforts to control public expectations. The modern chief executive has become a direct communicator with the public, in order to manage and control public attitudes effectively. The skillful use of the press, radio, and television by chief executives invites identification, which can then be used as a political weapon against resistant and parochial bureaucracies, groups of legislators, or group interests.

Research on executive behavior

Some twenty years ago a shock of realization occurred among students of executive behavior with the discovery that executive behavior deviated from its institutional prescriptions and descriptions. The rigid compartmentalization of government action implied in the separation of powers was found not to exist in fact. This principle, regarded by Montesquieu and Locke as a cardinal check to absolute power, did not realistically describe what occurred. Executive and legislative action closely interpenetrated. Moreover, the modern nation-state more and more demanded the closer integration of these functions, rather than their separation.

Dichotomous categories such as "politics" and "administration" were found to be inaccurate and insufficient for the explanation of decision making. "Administrative" behavior was found to be, not a discrete type of behavior, distinct from "political" activity, but part of a continuous stream of action in a large-scale organizational environment. [See ADMINISTRATION.]

While such older categorizations were thus discredited, newer concepts and models were developing, of deeper and more empirical explanatory power. Decision making and systems theory were two such models. Herbert Simon, Richard Snyder, and others elaborated decision-making models that dissected the individual, organizational, and situational components of decision making and linked them together in causal propositions. The focus of analysis shifted away from the policies themselves toward the complexities of the processes of policy making. The "how" of decisions gave more significant clues to the organization of influence in modern governmental structures than the metaphysical "what."

Not all effort was bent on model building. Much analysis of executive behavior took the form of case studies. Many of these were narrative and descriptive, designed to illustrate and depict the variegated paths of policy formation. Some contended that many of these case studies relied on recollection, hearsay, and other questionable evidence and therefore could not be considered more than illustrative. They were also criticized for their overemphasis on the idiosyncratic and the unique, a fragile basis for theory building. Despite such limitations, in the building stages of more systematic analysis, case studies communicated a sense of executive milieu that contributed to suggestive hypotheses. [See PUBLIC ADMINISTRATION.]

Another approach in analyzing executive behavior proceeded from institutional frameworks and demonstrated how executive behavior departed from such institutional presumptions. The work of Richard Neustadt and Don Price, among others, exemplified this category. This type of analysis was rich in insight about the interplay between the less formal and more formal factors which condition and influence executive authority.

Situational analysis. Still another way of analyzing executive behavior stressed situational factors. It proceeded from the multirole character of executive behavior in its organizational context as it confronted characteristic problem situations. Illustrative of this are the following situational typologies, derived from American governmental experience.

Executive decisions may be divided into three situational types: (1) crisis situations; (2) programmatic situations; (3) anticipatory situations. In each situation interest groups, the executive, and the presidential elite play varying roles.

Crisis situations. Under crisis conditions, public opinion is more aware of the situation, but legislative and interest-group involvement is less than in programmatic or anticipatory situations; and in these stress situations, executive discretion is greatest.

Crisis situations, which have become quite frequent in the post-1945 world, can be categorized as follows: bargaining crises (e.g., industrial disputes); legitimacy crises (e.g., the dismissal of MacArthur); crises of norms (e.g., scandals of various kinds, such as the Profumo affair); and, by far the most frequent and serious, national defense crises (situations which acutely threaten resources regarded as essential to national safety, e.g., the Cuban missile standoff and the Berlin airlift).

In crisis situations each system, in varying degrees, loses some of its pluralistic safeguards as

the executive assumes broad discretion. The executive acquires exclusive control in defining the situation and in directing the appropriate measures. The normal institutional workings of decision making are reduced to an executive directorate consisting of a handful of people. The public is anxiously alert but little informed, while the legislative bodies and interest groups assume passive roles. In sum, crisis situations bring structural changes in the system that give the broadest of authority to the executive. [See CRISIS; CRISIS GOVERNMENT.]

Programmatic situations. Programmatic situations demand long-range and broad-gauge policies. They require strategic determinations of ends and means. When programmatic issues are faced, a moderate degree of legislative and bureaucratic involvement results and executive discretion is limited. The Marshall Plan of the United States and the European Defense Community decisions by European governments are examples.

Anticipatory situations. Anticipatory situations concern eventualities, not immediate situations. The likelihood of occurrence may not be great, but should the situation occur, a course of action will have been decided upon. Of all situations, these evoke the greatest legislative debate, the least public awareness, and the greatest interest-group concern. Executive discretion is severely limited under these conditions, because the costs of inaction are difficult to foretell and the consequences are not close at hand.

Anticipatory situations are the result of previous crises. For example, the depression of the 1930s gave rise both to legislation and to administrative policies that anticipated a recurrence and were therefore designed to come into play when economic danger signals appeared. Programs such as the federal insurance of deposits in savings banks and the public works agendas to be used when unemployment reaches certain levels were created.

Problems of executive behavior

Within the three situational configurations described above, there are problems of executive behavior which flow from certain structural features of the system itself. Insufficient recognition has been given to the subgroups within the executive. It is traditional to think of the executive and governmental bureaucracy in hierarchic terms. In this view, the president or prime minister stands at the pinnacle of the executive, and below him are the administrators, ranged in a descending order of subordination. The enlargement of executive scope gave rise to centrifugal tendencies that diffused executive influence. The bureaucracies,

which ostensibly enlarge executive jurisdiction, in fact dilute and disperse executive influence. These bureaucratic groups have their own biases and often act autonomously and at variance with executive policies.

As a result, a problem that executives face is the "horizontal bargaining" within the executive. Not uncommonly the executive has to negotiate with his nominally subordinate agencies. Governmental bureaucracy is pluralistic, so that each bureaucracy has its own subvalues. Out of the long-accrued interdependence between the bureaucracies and legislative and economic interests, the bureaucrats have gained considerable independence of executive authority, and a growing political division occurs between the executive and the governmental bureaucracies normally under his jurisdiction. The internal politics of the executive in decision making has, perhaps, become more significant than executive-legislative relations. [See BUREAUCRACY and CIVIL SERVICE.]

At the outset of this article, the integrating and innovating functions of executive leadership in all political systems were stressed. These functions are closely related to the expectations of executive programs, i.e., the definition of broad political goals and specific legislative and administrative measures necessary to their fulfillment. Broad and consistent national programs for economic stability and growth, foreign policy strategy, defense postures, and welfare goals are expected of the chief executive. It is through these that the executive defines the situation for all the political actors.

The winning of acceptance for these programs demands accommodation to various political subgroups, whose focus is less on the general societal effects of legislative and administrative proposals than on the special effects these have upon their particular interests. This accommodation to specialized publics and interests is a serious executive problem. The "politics" of executive behavior is largely a matter of finding some synthesis, i.e., identity of interest or complementarity of roles, between the general viewpoint of the executive and the particular perspective of various groups.

In sum, despite institutionalized continuities, executive decision making forms not a single pattern but several situational patterns, in which the roles of bureaucracies, interest groups, parties, and legislators vary. The increase of both secular and acute crises has more sharply differentiated these modes of executive decision making.

The study of executive decision making reveals the several configurations of political systems as they respond to situational demands. In an era so

prone to crisis as the present, the far-reaching consequences of crisis decision making deserve fuller attention than they have yet received. As we have seen, crisis decision making is not merely a slight shift but a change in configuration of the system itself. Studies are needed, both of these structural changes and of certain secondary effects, such as changes in elite recruitment, responses of the various bureaucracies, and capabilities of the executive for prompt decision making.

The subject of leadership and executive behavior in general should draw the increasing attention of social scientists. The gap between the significance of executive behavior and current explanatory methods calls for greater research attention. The wide use of aggregate data about executive behavior and of direct empirical studies of executives in various systems has not seriously begun. If executive centralization is the trend, it must be carefully analyzed so that its processes and consequences are better understood.

LEARNING

In addition to the general articles under this heading, broad fields of learning phenomena are reviewed in FORGETTING; IMITATION; IMPRINTING; THINKING. More specific concepts relevant to learning are discussed in CONCEPT FORMATION; DRIVES; FATIGUE; INTELLIGENCE AND INTELLIGENCE TESTING; MOTIVATION; PROBLEM SOLVING; REASONING

AND LOGIC. *The role of learning in personal development is discussed in DEVELOPMENTAL PSYCHOLOGY; INTELLECTUAL DEVELOPMENT; LANGUAGE, article on LANGUAGE DEVELOPMENT; MORAL DEVELOPMENT; SENSORY AND MOTOR DEVELOPMENT; SOCIALIZATION. The role of learning in society is treated in ADULT EDUCATION; EDUCATION; EDUCATIONAL PSYCHOLOGY; INTELLECTUALS; KNOWLEDGE, SOCIOLOGY OF; LITERACY; TEACHING; UNIVERSITIES. The importance of learning is also emphasized in MENTAL DISORDERS, TREATMENT OF. Theories of learning are discussed in GESTALT THEORY; INFORMATION THEORY; LEARNING THEORY; MODELS, MATHEMATICAL. Some applications of learning are discussed in BRAINWASHING; COMMUNICATION, MASS; COMMUNICATION, POLITICAL; PERSUASION; PROPAGANDA. The measurement of learning is discussed in ACHIEVEMENT TESTING; INTELLIGENCE AND INTELLIGENCE TESTING; RESPONSE SETS. Of direct relevance to learning are the biographies of BEKHTEREV; GUTHRIE; HULL; MONTESSORI; PAVLOV; SECHENOV; TOLMAN; WATSON.*

I INTRODUCTION

Learning has been defined (Kimble 1961) as a relatively permanent change in a behavioral tendency, which occurs as a result of reinforced practice. One purpose of this definition, as with any definition, is to delimit as precisely as possible a particular realm of discourse. Thus, a word or two appears to be in order with respect to topics that this definition specifically includes and excludes.

Changes in behavior occur as a result of many processes, not all of which are forms of learning. The above definition succeeds in eliminating most if not all of these changes. Behavioral changes occurring as a result of maturation are ruled out by the requirement of dependence upon practice. Changes resulting from motivational fluctuations are temporary and are eliminated by the reference

to a permanent change. Changes in behavior that come under the heading of forgetting and experimental extinction are excluded by the reference to reinforced practice. Learning necessitates the appropriate use of reward or punishment. If these operations, collectively called reinforcement, are omitted, learning disappears; experimental extinction or "unlearning" takes place. The reference to reinforced practice is necessary to exclude such changes from the definition of learning.

Turning now to matters that the definition does not exclude, it should be noted that the definition says nothing about the kinds of behavioral changes that qualify as learning. There is, for example, no suggestion that learning always leads to an improvement in behavior: bad habits as well as good habits are encompassed by the definition. Similarly, acquired motives, attitudes, and values come within the scope of the definition as easily as do changes in language habits and motor skills. Finally, the use of the term "tendency" allows the definition to cover cases in which the products of learning do not immediately appear in performance. In this way the definition covers the numerous cases in which an individual learns something that may not be put to practical use for years. Someone might learn as a boy scout that moss typically grows on the north side of trees and that this information may be used to find one's way out of a forest when lost, but not actually perform any responses based on this information until much later, if ever. The distinction implicit in the previous statements, that between learning and performance, is basic to the psychology of learning. In general, learning refers to the establishment of tendencies; performance refers to the translation of these tendencies into behavior.

Historical background. Although ideas basic to the modern psychology of learning have existed for millennia, especially in the associationistic philosophies, the immediate antecedents of the scientific study of learning are to be found in the work of three scientists writing in the late nineteenth and early twentieth centuries: the German Ebbinghaus, the Russian Pavlov, and the American Thorndike [see EBBINGHAUS; PAVLOV; THORNDIKE].

Ebbinghaus. Ebbinghaus fathered the study of verbal rote learning (1885). As materials, he used meaningless three-letter, consonant-vowel-consonant, sequences, which have come to be called nonsense syllables. GOC, TER, and BIV are examples. Ebbinghaus constructed lists of these materials of various lengths, memorized them under various conditions, and attempted to recall them after various amounts of time. He discovered many

of the laws of such learning, which remain valid today. It is of incidental interest that Ebbinghaus also appears to have been the first psychologist to make use of the ideas of statistics and probability.

Pavlov. Using dogs as subjects, Pavlov studied the simple form of learning that we now call classical conditioning (1927). The Pavlovian procedure consisted of presenting the dog with food or an acid solution, which made the animal salivate, shortly after the presentation of some neutral stimulus, such as a tone or light, which did not. After several such pairings, the dog came to salivate at the presentation of the neutral stimulus as if that stimulus had somehow become a substitute for food or acid. Pavlov was able to demonstrate many of the basic phenomena of conditioning. He also developed a quasi-neurological theory to account for such learning.

Thorndike. Thorndike also worked with lower animals, such as dogs, cats, and chickens, and studied what we now call instrumental learning. The most famous of Thorndike's studies were those in which cats learned to operate a latch to escape from a puzzle box and to obtain a bit of fish outside (Thorndike 1898–1901). On the basis of his observations in these studies, Thorndike was led to develop an influential theory of learning in which three hypotheses were central: (1) learning consists of the formation of connections between stimuli and responses; (2) learning is a gradual rather than a sudden or insightful process; and (3) learning depends not just upon practice but also upon reward and punishment. This last hypothesis Thorndike called the law of effect.

Taxonomy of learning

As these historical materials indicate, the scientific study of learning involves the use of widely different procedures. It is useful, in fact, to differentiate forms of learning in addition to those described above. The most important of these are considered here.

Classical conditioning. Many investigators make a distinction between forms of learning in which the subject's reactions lead to reward or punishment and those in which such events take place independently of the subject's behavior. The former arrangement defines instrumental learning; the latter identifies classical conditioning. The four most important aspects of the classical conditioning experiment may be described by referring to the example of Pavlovian conditioning mentioned above.

(1) *Unconditioned stimulus (US)*—any stimulus that at the outset of an experiment produces

a regular reaction. In the typical Pavlovian experiment the US is food.

(2) *Unconditioned response (UR)*—the consistent reaction evoked by the US just referred to. In the Pavlovian experiments this was the salivation.

(3) *Conditioned stimulus (CS)*—a neutral stimulus paired with the US for experimental purposes. In the typical Pavlovian experiments, this was a light, buzzer, bell, or ticking metronome.

(4) *Conditioned response (CR)*. After several pairings of the CS and US, a response resembling the UR may be elicited by the conditioned stimulus. This is the conditioned response, conditioned reaction, or conditioned reflex.

Studies of the conditioned reflex show that such learning is a very general process. Reactions that have been conditioned, in addition to salivation, include the galvanic skin response, the eyeblink, a blocking of the alpha rhythm of the brain, pupillary dilation, vasodilation and constriction, and secretion of various internal organs. It has also been demonstrated that the range of neutral stimuli to which such conditioning may take place is wide and includes all of the stimuli that the organism ordinarily perceives and some that it ordinarily may not perceive.

In discussing classical conditioning, two items of interpretation appear to be important. First, as the responses listed above suggest, the reactions modifiable by classical conditioning are often emotional reactions. Thus, classical conditioning appears to be the mechanism by which hopes, fears, attitudes, and other emotionally toned reactions are established. Second, it is important to restrict the application of the term "conditioning" to classical conditioning. The extension of the concept of conditioning to almost every form of learning, as some authors have done, leads to confusion.

Simple instrumental learning. Most learning situations differ from classical conditioning in that the organism's reactions are instrumental to the securing of reward or the avoidance of punishment—hence the name "instrumental learning." In purely physical terms, there are four possible relationships between a given response and reward and punishment: the response in question may (1) produce reward, (2) avoid a punishment, (3) lead to punishment, or (4) lead to the withholding of reward. The great majority of experimental work in simple instrumental learning involves the first two of these, reward learning and avoidance learning. We shall discuss reward learning here, postponing the treatment of avoidance learning until later.

A common device for the study of reward learning is the Skinner box. A representative version of this apparatus might consist of a chamber about one foot on a side. A lever extends into the box on one side. If the rat (the species most commonly studied in the Skinner box) presses the lever, a bit of food or a small dipper of water is automatically presented.

Investigations of simple instrumental learning employ two general procedures: free responding and discriminative. In the latter method a distinctive signal such as a light or tone or the insertion of the lever into the box is used to indicate when reward is available. If the animal presses the bar in the presence of the discriminative stimulus, reward occurs. Bar pressures at other times go unrewarded. In the free-responding situation, there is no discriminative stimulus to indicate when reward is available.

Schedules of reinforcement. Most investigations of learning in the Skinner box employ the free-responding procedure and some version of a partial-reinforcement schedule. The rat does not receive reward for every bar depression but is reinforced on a schedule that is defined either in terms of a temporal interval or in terms of a specified number of responses. Thus, there are both interval and ratio schedules of reinforcement. Moreover, the number of responses required for reinforcement or the temporal interval separating reinforcements may be fixed (regular) or variable (irregular). The combinations of these physical arrangements generate four basic schedules of reinforcement: (1) fixed interval, (2) variable interval, (3) fixed ratio, and (4) variable ratio. In the fixed interval schedule the animal is reinforced for the first response after a standard period of time, perhaps one minute. In the variable interval schedule the animal is rewarded for the first response after some average amount of time, such as one minute, but the intervals separating successive reinforcements vary widely around this average value. Similarly with ratio schedules, the fixed ratio schedule is one in which the animal is reinforced for the n th (for example, the fifteenth) response and the variable ratio schedule provides reward after some average, but varying, number of bar depressions. These schedules of reinforcement produce characteristic behavioral patterns that cannot be described within the scope of this article. The interested reader is referred to Skinner (1938), Ferster and Skinner (1957), or to any standard book on learning (for example, Hall 1966; Kimble 1961). One practical consequence of any partial reinforcement schedule is the estab-

lishment of great persistence in behavior. This is particularly true of the variable interval schedule. This schedule, therefore, is widely used in experiments in which many tests must be conducted. The investigation of stimulus generalization, which we shall discuss later, and the influence of drugs upon behavior are important examples.

Complex instrumental learning. The simple experimental situations typified by the Skinner box are relatively recent in the history of the scientific study of learning. Earlier investigations tended to use more complex situations, the multiunit maze being, by far, the most popular. The general abandonment of these procedures probably resulted from two difficulties: the complex instrumental learning situations were difficult to subject to automation; and, more importantly, the learning that takes place in such situations is so complex as to defy analysis. On the other hand, investigations of complex instrumental learning did lead to a preliminary statement of certain laws of learning and to the development of certain important concepts. One of the most important items in the first category was suggested by the fact that mazes tend to be learned in a backward order; the correct turns near the goal are learned first, and those near the starting point are learned last. This fact implies the existence of a *goal gradient* or delay of reinforcement gradient, which means that responses followed immediately by reward are learned more rapidly than those for which reward is delayed.

Habit family hierarchy. The most useful general concept to come from the study of complex instrumental learning is that of habit family hierarchy. Investigators of maze behavior, for example, noticed that the initial behavior of the rat in the maze was not merely random wandering but revealed certain dependabilities. The rat might show a consistent tendency to turn right rather than left, to proceed straight ahead rather than to make a turn at all, to prefer dim alleys to those more brightly illuminated, and to choose paths leading in the general direction of the home cage over those that lead in the opposite direction. Such observations suggested the general proposition that the learner comes to the learning situation with a repertoire of responses (habit family) that vary in strength (hierarchy). This made it possible to view complex instrumental learning as a reorganization of the habit family hierarchy.

Acquisition of motor skill. At the human level, an important form of learning is the acquisition of motor skill. Improvements in handwriting, baseball pitching, piano playing, and bicycle riding are familiar examples. The only caution that should be

urged is that it is important to distinguish between skills that emerge as a result of learning and those that appear as a result of maturation. In the young child, walking is an example of the latter type of skill. Although we speak of "learning to walk," experimental studies have shown that this skill is almost entirely the result of maturation and that practice has relatively little to do with it.

As is the case in all other areas of learning, laboratory study has led to a refinement in methods and to the use of relatively standardized procedures. A very commonly used device for the study of motor learning is the pursuit rotor (rotary-pursuit apparatus). The pursuit rotor resembles a phonograph turntable. Its main feature is a motor-driven disc, which usually turns at the rate of 60 rpm. At a distance of four or five inches from the center, there is a small target approximately the size of a dime. The subject's task is to keep the point of a hinged stylus in contact with the target while the disc rotates. The measure of performance is the amount of time the subject keeps the point of the stylus in contact with the target.

Massed versus distributed practice. Some of the most important results obtained from pursuit rotor studies deal with the spacing of practice trials. In one investigation (Kimble & Shatel 1952), subjects received fifteen 50-second trials per day for ten days (see Figure 1). One group learned under conditions of massed practice, in which the trials were separated by 10-second rest pauses. The other group learned under conditions of distributed (spaced) practice, the trials being separated by rest pauses of 70 seconds. The results of the investigation were as follows: (1) Massed practice produces a serious interference with the acquisition

Figure 1 — Learning curves for a pursuit rotor task under spaced and massed practice

Source: Kimble & Shatel 1952, p. 356.

of pursuit rotor skill. (2) Under either condition of practice, improvement continues for a long time. In Figure 1, it can be seen that even after 150 trials, the subjects under both conditions of practice still continue to show improvement. (3) The initial trials on any day's session show certain interesting characteristics. One of these is the phenomenon of warm-up, which is most conspicuously displayed in the later sessions of the subjects who learn under distributed practice. The first trials are quite inferior to the final trials of the preceding day, and it may take six or eight trials for the warm-up process to be complete and for the level of performance of the previous day to be reached. (4) Under conditions of massed practice, a different effect may appear at the beginning of each practice. This is an improvement in performance that apparently occurs as the result of rest and the disappearance of a fatiguelike state produced by massed practice. This phenomenon is most obvious in the early sessions under massed practice. In Figure 1 the straight lines through the massed-practice functions are fitted curves used to estimate what performance would have been on the first trial of a particular session if a day's rest had not intervened (open circles) and what it would have been on that same trial if there had been no need to warm up (filled circles). The difference between the open and closed circles is a measure of this improvement, technically called *reminiscence*. It is of interest that in this experiment *reminiscence* disappears late in learning. (5) If these subjects, who practice with their preferred hand, are tested for performance with their nonpreferred hand and if appropriate control procedures are employed, it is possible to demonstrate that the performance of the nonpreferred hand benefits considerably from practice with the preferred one. This characteristic of motor learning, called *transfer of training*, is very conspicuous in motor skills.

Rote verbal learning. As was mentioned at the outset of this article, one of the earliest forms of learning to receive scientific study was verbal learning, which Ebbinghaus began to investigate in the late nineteenth century. In its modern form the study of verbal learning takes two major forms, *serial learning* and *paired-associate learning*. *Serial learning* involves the memorization of lists, typically lists of nonsense syllables; *paired-associate learning*, as the name implies, involves the learning of pairs of items in the way one learns a foreign language vocabulary.

Both of these forms of rote learning are influenced in the same way by certain variables:

(1) The manipulation of distribution of practice

Figure 2 — A characteristic serial position function

leads, as in motor learning, to better performance under spaced practice than under massed practice, but typically the effect is of a much less impressive magnitude than in motor learning. (2) Both proceed much more rapidly with meaningful materials (for example, a list containing the words *house, robin, wagon, money, uncle*, etc.) than with nonsense materials (for example, a list containing the items TOZ, LUN, GIB, VLR, DEG).

Studies of serial learning have revealed characteristic differences in the ease of learning different portions of the list. The very first items are easiest; those at the end are next easiest, the most difficult items are those just after the middle of the list. This phenomenon, illustrated in Figure 2, may be referred to as a serial position function.

Interference phenomena. The paired-associate learning procedure has been particularly useful in the study of interferences of the kind thought to be responsible for normal forgetting. Suppose a subject learns the following pairs of words:

table—bright
dozen—forest
value—camel
willow—stone
label—graze

He then learns these pairs:

table—lozenge
dozen—tempest
value—blister
willow—horse
label—trial

Note that the stimulus words are the same in the two lists but that the responses are different. Re-

ferring to the stimulus and response words in the first list as *A* and *B*, respectively, the items in the second list can be referred to as *A* and *C*. This *A-B*, *A-C* relationship leads to great difficulty in remembering the *A-B* associations. The establishment of such interferences is commonly thought by psychologists of verbal learning to be the essential condition for forgetting.

Learning to learn. If subjects are required to learn a series of lists of verbal materials, they show a steadily improving ability as a function of the number of lists previously committed to memory (unless, as just noted, the lists are constructed to interfere with each other). The results typically obtained in experiments on learning to learn appear in Figure 3. Among the most important experimental demonstrations of this fact are the investigations of Harlow (1949). Harlow taught monkeys a series of several hundred discrimination

Figure 3 — Hypothetical function depicting "learning to learn" in a typical rote learning situation

problems. During the course of this experiment, the subjects improved to the point where they were solving new discriminations after just one trial.

Basic phenomena of simple learning

Most students of learning assume that the variety of forms of learning considered in the previous section all obey the same basic laws. For this reason, it has seemed expedient to most such students to study the basic properties of learning in simple situations, often with lower organisms as subjects. Thus, realistic presentations of what are regarded as the basic phenomena of learning (this section), as well as of its most fundamental laws (next section), must depend heavily upon studies of classical conditioning and simple instrumental learning.

Acquisition and the learning curve. During the course of practice, a subject's performance changes in a direction that indicates an increase in the

strength of the underlying process. The phenomenon of habit acquisition is often represented in the form of a learning curve. The shape and direction of such functions depend upon the particular measure of learning employed. Idealized but typical functions appear in Figure 4. In what fol-

Figure 4 — Characteristic forms of learning curves for four different measures of performance

lows, we shall limit ourselves to a report of investigations where increases in the measure plotted reflect increases in the strength of a habit.

Extinction. As mentioned earlier, and as will be developed in more detail later, learning requires the use of reinforcements; for example, allowing the subject the opportunity to obtain food or avoid punishment for performing the response to be learned. The omission of reinforcement leads to a reduction in performance that Pavlov called experimental extinction and is now more often referred to simply as extinction.

Spontaneous recovery. If, following extinction, the subject is allowed a period of rest, there frequently occurs a spontaneous increase, or spontaneous recovery, in the strength of the previously extinguished response. This increase resembles the increase called reminiscence, which occurs in motor learning. Many theorists (for example, Hull 1951) regard both as reflecting the dissipation of some type of inhibitory process. What next happens to the strength of the spontaneously recovered response depends upon whether or not it is reinforced. The reintroduction of reinforcement leads to the rapid re-establishment of the full strength of the response. Omission of reinforcement leads to re-extinction. Figure 5 provides a graphic summary of the phenomena described.

Stimulus generalization. Ordinarily, in a conditioning experiment the conditioned stimulus is precisely controlled. If the response is tested with other stimuli, the conditioned reaction may occur but in diminished strength. For example, Guttman and Kalish (1958) trained pigeons to peck at a disc illuminated with a light of 550 m μ and tested the reaction of the pigeon to lights of other colors. The measure of response strength employed was the rate of pecking. These investigators obtained results indicating that there is a generalization gradient (Figure 6 illustrates these findings). In general, such a gradient shows the transfer of response strength to stimuli similar to the training stimulus and a reduction in strength that is proportional to the difference between the training and test stimuli.

Discrimination. The tendency for a response to generalize means that the subject fails to discriminate between similar stimuli. Discrimination between two stimuli may be obtained by presenting the two stimuli either together (allowing the organism to choose one) or in succession (allowing the organism to respond or not) and reinforcing responses to one stimulus and withholding reinforcement for responses to the other, provided that the organism's sensory mechanisms can detect the difference. Following such training, the subject

Figure 5 — Summary graph depicting acquisition, extinction, spontaneous recovery, reconditioning, and a second extinction

typically learns to respond to the reinforced stimulus but not to the other. It is clear that the establishment of a discrimination involves all of the basic phenomena discussed so far: Responses to the reinforced stimulus are *acquired* and then *generalized* to the nonreinforced stimulus. These latter responses are *extinguished* by nonreinforcement but presumably are subject to spontaneous recovery.

Concept formation. At a level much more complex than that of simple learning, it seems very likely that the formation of concepts entails a

Figure 6 — A generalization gradient

process of discrimination learning. A concept obviously involves a tendency to treat diverse things as *identical* (generalization) but to limit the extent of such indiscriminate reaction.

The laws of learning and performance

The major preoccupation of students of learning has been with the experimental manipulation of a variety of variables in an effort to determine their lawful relationship to learned changes in behavior. As we shall see, it is easy to list variables that have powerful effects upon performance in the learning situation. What is not so easy is to determine with certainty whether the effect is upon *learning* or *performance*. To illustrate this difficulty, suppose that two groups of rats learn a maze under conditions that are exactly alike except that one group learns after having been deprived of food for 24 hours and the other group learns after having been deprived of food for only 2 hours. The learning curves obtained on these two groups of subjects would surely be very different (see Figure 7). But is this difference a difference in learning or performance—or both? The obvious way to find out is to subdivide each group at some point when an impressive difference in behavior has been established, testing some previously very hungry animals when they are only moderately hungry and some previously moderately hungry animals when they are very hungry. Under controlled conditions and with the change in motiva-

tion, the performance of both groups changes immediately to what it would have been if the new condition of motivation had prevailed from the beginning (see Figure 7). In short, there is no evidence that motivation has any effect upon learning in an experiment of this sort. The influence, which is a powerful one, is entirely upon performance.

The difficulty in the experiment just described exists for every other variable that might be manipulated. Thus, in the sections to follow, we shall present several important regularities emerging from the experimental study of learning; but, except in connection with the first of these, we shall not return to the question whether the effect is on learning or performance. It will be sufficient to say that the current trend in the thinking of psychologists of learning is to assign more and more of these variables a role as determiners of performance rather than of learning.

Number of practice trials. By definition, learning depends upon practice; and it is obvious that the amount of practice must figure in some way in

determining the amount of learning. There is considerable argument, however, about the kind of law involved (Kimble 1961, pp. 109-136). Some psychologists have maintained that all learning is, in some sense, insightful and occurs in just one trial; others have insisted that all learning represents the gradual strengthening of some underlying process. The learning-performance issue is a concern chiefly of the theorists who maintain that all learning is basically insightful, for the fact of the matter is that most learning curves reflect gradual improvements in performance. The general way out of this paradox taken by insight theorists has involved the assumption that learning involves numerous subskills that are acquired suddenly but after different amounts of practice, producing the appearance of gradual learning.

Amount of reinforcement. Obviously a practice trial, among other things, provides an occasion for the administration of reinforcement. Several of the best established laws of learning relate to reinforcement in some way. It is known, for example, that the amount of reinforcement is an

On trial $N + 1$, one low-motivation group is switched to high motivation and one high-motivation group is switched to low motivation

Figure 7 — Hypothetical learning curves showing that the effect of motivation is on performance, not on learning

important variable. Up to some limit, increasing amounts of reinforcement lead to improvements in performance, the characteristic function being negatively accelerated. The same results have been obtained for quality of reinforcement. Subjects learn more rapidly for a highly desirable reinforcer than for a less desirable one.

Delay of reinforcement. It is now well established that the time separating a response and its reinforcer is a very powerful variable in determining the progress of behavioral change in a learning situation. In general, the longer reinforcement is delayed following the execution of the response, the slower the rate of such change. What is most surprising in the results of such studies is that when extraneous sources of reinforcement are eliminated (for example, Grice 1948), it has been found that little if any learning occurs with delays greater than four or five seconds.

Secondary reinforcement. This last fact, of course, raises the question of what mechanisms have been at work in experiments in which subjects have learned with a fairly long delay of reinforcement. The commonly accepted answer is in terms of secondary reinforcement. A discussion of the details of secondary reinforcement would lead us far afield, but fortunately a nontechnical presentation of the argument will suffice. Suppose a rat runs a maze and at the end is restrained in a delay chamber for five minutes before being allowed access to the food used as a reinforcer. Suppose, further, that the rat learns the maze under these conditions, which obviously involve a delay of reinforcement much greater than the four or five seconds mentioned above. How are these two sets of facts to be brought into harmony? The argument in terms of secondary reinforcement goes this way: Cues in the delay chamber come to stand for food because they are always present just before food becomes available. Since these cues stand for food, they have some of the same characteristics as food, including the important characteristic of functioning as (secondary) reinforcers. Thus, the cues in the delay chamber serve as immediate (secondary) reinforcers and promote the progress of learning. The obvious implication of this argument is that if the cues preceding reinforcement varied from trial to trial, so that no stable association could be formed, there would be a serious disruption in the progress of learning.

The delay of reinforcement gradient is basic to the theoretical interpretation of a variety of phenomena in learning. For example, the backward order of elimination of blinds in a complex maze referred to earlier probably reflects the operation

of this gradient. A gradient with all the features of the delay of reinforcement gradient also seems to apply to punishment. Miller (for example, 1959) has developed a theory of approach-avoidance conflict that is based on simultaneous operation of gradients based on reward and punishment.

The interstimulus interval. The experiments on delay of reinforcement described in the preceding section were all experiments in instrumental learning. A related variable in classical conditioning is the time between conditioned and unconditioned stimuli, often referred to as the interstimulus interval. Studies of this variable have produced relatively consistent results, which Figure 8 presents graphically. Two features of the interstimulus interval are important: (1) Backward conditioning, in which the unconditioned stimulus precedes the conditioned stimulus, leads to little or no conditioning. (2) The function for forward conditioning, in which the conditioned stimulus precedes the unconditioned stimulus, displays a conspicuous optimal interval; intervals either longer or shorter than the optimum produce inferior conditioning. For many response systems the optimal interval is in the neighborhood of .5 second. Recent investigations suggest that this optimal interval is more limited than was once thought. These studies (for example, Noble & Adams 1963; Noble & Harding 1963) have tended to indicate (1) that for lower animals the optimal interval is longer than .5 second and (2) that its duration may be different at different points in practice.

Other variables. The variables described above are representative of those studied in investigations of simple learning. A complete catalogue of such variables is beyond the scope of this report. Thus, we shall supplement the foregoing review by

Figure 8 — A characteristic interstimulus interval function

simply mentioning certain other variables and only briefly indicating their effect upon performance.

Motivation. As we have seen, motivation ordinarily facilitates performance in the learning situation. In some circumstances, however, motivation may energize tendencies that interfere with the response to be learned. Under these circumstances, motivation, particularly very strong motivation, may appear to interfere with learning.

Distribution of practice. As we have also seen, distribution of practice usually favors rapid learning. In some complex tasks, however, massed practice may aid in the elimination of initial errors and briefly speed the progress of learning.

Intensity of the unconditioned stimulus. The intensity of the unconditioned stimulus in classical conditioning behaves as the amount of reinforcement does in instrumental learning; the greater the intensity of the unconditioned stimulus, the more rapidly conditioning proceeds.

Intensity of the conditioned stimulus. The intensity of the conditioned stimulus usually has little effect on the speed of conditioning; but recent studies (Grice & Hunter 1964) show that when strong and weak conditioned stimuli are used in the same experiment with the same subjects, the effectiveness of this variable increases considerably.

A final point is that the effects of the variables mentioned in this and the preceding section interact; that is, the effect of one depends upon the values of the others. The precise nature of the interactions remains to be worked out for almost all combinations of variables.

The nature of reinforcement

The major theoretical issues in the psychology of learning are traceable to the opinions of E. L. Thorndike. As mentioned earlier, from Thorndike's studies of cats in a simple instrumental learning situation, Thorndike developed three important hypotheses about the nature of learning: learning is gradual rather than sudden; learning consists in the formation of stimulus-response connections; and at bottom, reinforcement entails the operation of rewards and punishments. This last idea is the one that we shall develop most fully in this section. As Thorndike put it:

The Law of Effect is that: Of several responses made to the same situation, those which are accompanied or closely followed by satisfaction to the animal will, other things being equal, be more firmly connected with the situation, so that, when it recurs, they will be more likely to recur; those which are accompanied or closely followed by discomfort to the animal will, other things being equal, have their connections with that situation

weakened, so that, when it recurs, they will be less likely to occur. The greater the satisfaction or discomfort, the greater the strengthening or weakening of the bond. ([1898-1901] 1911, p. 244)

This statement came in for severe criticism on two particular counts: (1) It was criticized as subjective and unscientific in that the terms "satisfaction" and "discomfort" appeared to entail commitments to a mentalism that the psychology of 1911 was struggling to escape. Thorndike, however, was on safer methodological ground than his critics realized for he offered a means of objectifying these terms that we find perfectly acceptable today. "By a satisfying state of affairs is meant one which the animal does nothing to avoid, often doing such things as attain and preserve it. By a discomforting or annoying state of affairs is meant one which the animal commonly avoids or abandons" ([1898-1901] 1911, p. 245).

(2) The law of effect was criticized as circular: that is, learning to approach some object (for example, food) could define an object as a satisfier that, in turn, could be used to explain the learning that served to define it as a satisfier in the first place. Although Thorndike himself was not particularly clear on how to deal with this criticism, later advocates of his general point of view (for example, Miller & Dollard 1941) provided an answer. In general, this answer is that the transparent circularity in the example above disappears when it is understood that the definition of a satisfier in a defining experiment of the type proposed by Thorndike establishes the object as a general satisfier that will function as a reinforcer in a variety of learning situations. That is, given that food functions as a reinforcer in one situation, it is possible to predict with a fair degree of certainty that it will function in a similar way in a host of others. The law of effect has survived these criticisms and now has become the position by which other interpretations of reinforcement are usually defined.

The law of effect. Before proceeding further with this discussion, it is important to make a distinction between empirical and theoretical versions of the law of effect. The empirical law of effect involves nothing more than the simple factual statement that there are objects, such as food, water, and escape from punishment, that function dependably as reinforcers. The theoretical law of effect, on the other hand, states (using Thorndike's terminology) that these events are reinforcers because they are satisfiers. Because of its factual status, the empirical law of effect is not an object of dispute. Arguments about the nature

of reinforcement involve the theoretical law of effect.

The statement that all reinforcers are satisfiers or annoyers is merely one of several proposals that have been offered as to the ultimate nature of reinforcement. For purposes of exposition, it is convenient to identify three general classes of such proposals, which we shall call tension-reduction theory, stimulatory theory, and reactional theory.

Tension-reduction theory. Tension-reduction theory maintains that the essential condition of reinforcement is the alleviation of a state of physiological or psychological tension. In the past, tension-reduction theory was so closely tied to Thorndike's theory that current usage tends to identify the law of effect with this position and often erroneously equates tension-reduction theory with reinforcement theory.

At different times, and in the hands of different authors, need-reduction, drive-reduction, and drive-stimulus-reduction theories of reinforcement have been offered. Need-reduction theory identifies reinforcement with the satisfaction of some physiological need (for example, food, water, or sex) that if not attained means that the individual or its species will perish. Although this theory is attractive because of its affinity to biological processes, certain facts make its acceptance impossible: (1) There are many rewards that appear to correspond to no biological need. These include rewards that satisfy such acquired motives as those for affection, dominance, and accomplishment. (2) Certain biological needs appear to involve no correlated reinforcer. One of these is the need for oxygen, which is present at very high altitudes but which does not seem to create a state of tension or drive. There is no evidence that the administration of oxygen under these circumstances is a reward.

Difficulties such as these led certain theorists (Hull 1943) to distinguish between need (a physiological condition) and drive (the psychological experience associated with needs) and to suggest that reinforcement is drive reduction rather than need reduction. We shall apply this distinction presently.

The drive-stimulus-reduction theory of reinforcement (Miller & Dollard 1941) suggests that drives are always intense stimuli and that drive reduction (assumed to be reinforcing) is a matter of stimulus reduction.

Stimulatory theory. Stimulatory theory maintains that particular stimuli are reinforcing and distinguishes itself from tension-reduction theory in these terms. Thus, food is a reinforcer because

of its taste (not because it reduces hunger), and water is a reinforcer because of the stimulatory aspects of drinking (not because it reduces thirst).

Reactional theory. Reactional theory stands in opposition to both tension-reduction theory and to stimulatory theory and holds that it is the act of eating or drinking, rather than taste or drive reduction, that is essential to reinforcement.

Experimental tests. Disagreements among these various interpretations of reinforcement have led, over the years, to a wide variety of experimental tests designed to establish the validity of one particular interpretation. Typically, tension-reduction theory has provided the point of departure, and adherents of opposing theories have attempted to strengthen their theoretical positions by discrediting tension-reduction theory. For example, Sheffield and Roby (1950) demonstrated that rats will learn to run a simple maze for a reward consisting of saccharine dissolved in water. The significance of this finding derives from the fact that saccharine has no nutritional value, being eliminated from the body chemically unchanged. This suggests that it must be either the sweet taste of saccharine (stimulatory theory) or the act of ingestion (reactional theory) that provides for reinforcement. Advocates of tension-reduction theory, however, were able to point out that although saccharine produces no reduction in need it may produce a reduction in drive. Thus, Miller (1963) reported that rats that were allowed to drink a saccharine solution subsequently ate less food than the control subjects, which were allowed to drink only water. Miller's interpretation was that the consumption of saccharine had led to a reduction of the hunger drive although obviously it had not altered the rats' need for food.

Similar problems for tension-reduction theory were provided by demonstrations that the opportunity to explore or to manipulate the environment is rewarding for lower animals. For example, Butler (1953) was able to show that rhesus monkeys will learn a discrimination for no other reward than the opportunity to see out of their normally closed cage. Other investigators (Harlow, Harlow, & Meyer 1950) demonstrated that monkeys learned to distinguish between manipulable and nonmanipulable objects apparently for no other reward than the opportunity to manipulate them. Still others (Kish 1955) showed that rats will learn a bar-pressing response to turn on a dim light or that they will learn a simple maze for the opportunity to explore a novel environment. For some of these demonstrations, but not all, tension-reduction theorists were able to deal with the prob-

lem by the postulation of a motive to explore or to manipulate and by the assumption that learning depended on the reduction of these drives. Obviously there are certain difficulties with such explanations in that they open the possibility of postulating a new motive for every demonstrable type of reward. On the other hand, it is known that some of these motives, for example, the exploratory motive, increase in strength with deprivation, as many other motives do. Such evidence makes the interpretation somewhat more acceptable in that it lends credence to the concept of an exploratory motive by providing independent evidence for it.

A special threat to tension-reduction theory has recently come in the form of demonstrations that rats will learn a variety of responses (the most common response is bar pressing) for a weak electrical stimulation of a variety of areas of the brain stem. The simplest interpretation of such a result is that such stimulation is somehow pleasant for the rat, and such demonstrations have been interpreted as a support for stimulatory theory. On the other hand, Olds (1958) has shown that the effectiveness of brain stimulation depends in part upon the level of the rat's hunger and sex drives. This opens the possibility that brain stimulation reduces these and other motives.

At the same time that tension-reduction theorists were dealing with these attacks upon their position, they were also providing more positive evidence in support of their own position. A typical experiment is that of Miller and Kessen (1952). These investigators demonstrated that rats learned a simple discrimination for a reward provided by the introduction of food directly into the stomach by way of a fistula. Such learning took place in the absence of taste stimulation emphasized by stimulatory theory and ingestive behavior emphasized by reactional theory. This appears to leave the alleviation of hunger (tension reduction) as the only remaining mechanism of reinforcement.

It is apparent that the variety of experimental tests described above did not succeed in establishing any particular theory as the obviously correct theory of reinforcement. This state of affairs has had two important consequences. One consequence is that certain theorists, most notably Collier (see, for example, Collier & Myers 1961), have made a strong case for the view that reinforcement entails a variety of mechanisms, probably all of those emphasized by the more specialized theories of reinforcement.

The other important consequence is the increased appeal of multiprocess theories of learn-

ing. Such theories propose that learning itself involves a number of subtypes and that the mechanisms of reinforcement differ for the various forms of learning.

Multiprocess theories. The most popular form of multiprocess theory is a two-process theory that maintains that the mechanisms of reinforcement are different for classical conditioning and instrumental learning. The position is that instrumental learning occurs as a result of reinforcement provided by tension reduction, whereas for classical conditioning all that is necessary is the contiguous occurrence of conditioned and unconditioned stimuli (or, in some versions, conditioned stimulus and unconditioned response).

One of the appealing features of two-process theory is the readiness with which it can be applied to avoidance learning, which is difficult to understand in terms of any single principle of reinforcement. Suppose we consider the following experimental arrangement: A rat is placed in a Skinner box and on each trial a light comes on and five seconds later an electric shock is applied to the animal's feet through an electrifiable grid in the floor, unless, in the meantime, the rat presses the bar. Rats are able to learn this response quite quickly. Two-process theory deals with this learning as follows. On the early trials, before the rat has learned to press the bar and avoid the shock, light and shock are paired on every trial as in classical conditioning. This pairing leads to a conditioning to the light of a fear reaction. On subsequent trials, the appearance of the light arouses fear in the subject, and this, in turn, leads to a heightened level of activity. In the course of such activity, sooner or later the animal presses the bar, terminating the light, reducing fear, and also avoiding the shock. The reduction in fear, which is contingent upon the cessation of the light, provides reinforcement for the bar-pressing reaction.

Psychopathology. Applications of learning theory to psychopathology, for example, those attempted by such theorists as Dollard and Miller (1950), have made important use of a two-process explanation in their descriptions of neurotic symptomatology. Phobias are often interpreted as direct or symbolic representations of classically conditioned fear reactions; and neurotic behavior is viewed as avoidance behavior motivated by fear and reinforced by fear reduction.

II

CLASSICAL CONDITIONING

Classical (or Pavlovian, respondent, or type-S) conditioning refers to any of a group of specific procedures that, when applied to an organism under appropriate conditions, result in the formation of the type of learned behavior known as the conditioned response. The term also refers to phenomena and relationships discovered through experiments using classical conditioning procedures. The adjective "classical" is used to distinguish these procedures from the more recently developed instrumental, or operant, conditioning procedures, which also lead to the formation of conditioned responses.

The Russian physiologist I. P. Pavlov was primarily responsible for the development of the methods and nomenclature of classical conditioning, and he discovered and described many of the most important associated phenomena (Pavlov 1927). The early writings of Pavlov had a profound influence on the development of behaviorism by John B. Watson, who considered classical conditioning to be the basis of acquisition of all learned behavior. The wide acceptance of behaviorism by American psychologists and the availability of two English translations of Pavlov's *Lectures on Conditioned Reflexes* (1923) in the late 1920s were followed by an increased and sustained output in the United States of published research on conditioning. However, most of this research was con-

ducted by psychologists who used instrumental techniques more often than they used classical conditioning. Although Pavlov's methods and data were behavioral in nature, he treated them as bearing directly upon the physiology of the cerebral cortex. His theory of conditioning is, therefore, a theory of brain function. (The present article, however, will deal mainly with its more behavioral aspects.) The Russian work on conditioning since Pavlov has very largely followed the pattern set by him.

Characteristics. The following characteristics are principal features of classical conditioning. A response already within the repertory of the experimental subject is designated the unconditioned response (*UR*) and the stimulus that evokes it is called the unconditioned stimulus (*US*). Another stimulus, one that does not elicit the *UR* or any response similar to it, is designated the conditioned stimulus (*CS*). The *CS* and the *US* are presented repeatedly to the subject, either simultaneously or with the *CS* preceding but overlapping the *US* in time. A response similar to the *UR* that develops to the *CS* is called the conditioned response (*CR*). The change in this response to the *CS* from an initial zero magnitude or frequency to a positive magnitude or frequency following practice constitutes a learned acquisition that is called conditioning.

Pavlov and his collaborators used the dog as their experimental subject. Salivation was the *UR* to the *US* of food or dilute acid. The *CS*s were lights, sounds, or pressures systematically applied to the skin, and the *CR* was salivation. But Pavlov discovered that the sights and sounds produced accidentally by the experimenter and his apparatus might also become *CS*s or interfere with the process of conditioning. He found it necessary to develop techniques and apparatus for collecting and measuring the magnitude and latency of the salivary *CR*s and *UR*s and for controlling the duration, magnitude, and time relations of the *CS*s and *US*s. These and similar procedures for isolation of the experimental subject and for control of the environment and measurement of responses are part of the technical procedures of classical conditioning.

Generality. Classical conditioning has very great generality. There is no apparent limit to the kinds of responses that can be conditioned in this manner or to the kinds of events that can serve as *CS*s. Any response that is evoked consistently by the *US* can be conditioned, and any stimulus that passes the initial test of neutrality can serve as a *CS*. Many stimuli fail this test, particularly when human beings are the subjects.

The generality of classical conditioning can be viewed also in terms of the level in the phyletic series and the chronological age of the organism in which conditioning first occurs. The few reports of classical conditioning of one-celled organisms have not been confirmed, and there is serious doubt that it is possible to achieve conditioning in these organisms. The evidence on conditioning of the worm is in similar confusion, and it is very doubtful that organisms without a true nervous system can be conditioned. With organisms higher in the phyletic series, who have a true nervous system, there is little question that they can be conditioned. Conditioning of infants of many species, including the human being, has been reported. There have also been reports of successful classical conditioning of the human fetus in the age range of 6.5–8.5 months.

Parameters of classical conditioning. It is possible to measure the latency, duration, and amplitude of a *CR* and also the frequency of its occurrence within a specified period of time. Ordinarily, only one or perhaps two of these measurements will be made concurrently, and whatever measure is applied to the *UR* will be applied also to the *CR* as a basis for comparison. Similar but not identical assessments of conditioning are obtained when different measures are used.

As conditioning develops over practice trials, the latency of the *CR* decreases, while the duration, the amplitude or magnitude, and the frequency of the *CR* increase. Eventually, each of these measures approaches an asymptotic level and does not change with further conditioning trials. The rates at which such asymptotic levels are approached vary with the measures used. It is common practice in experiments on classical *CR*s either to give all subjects an equal number of conditioning trials or to continue conditioning training until the same performance level has been attained by every subject. In the former case, individual differences between subjects show up in the variable level of conditioning attained, and in the latter case the differences appear in variations in the number of training trials required to reach the performance criterion. There are advantages and disadvantages to each of these procedures, but the results of any given experiment will depend upon this methodological consideration as well as upon the measurement procedures.

Temporal contiguity of stimuli. The rate or amount of conditioning and its relative difficulty are functions of the time relations between the *CS* and the *US*. Different names have been given to conditioned responses that are established under

different time relations of the conditioned and unconditioned stimuli.

Simultaneous conditioning. The simultaneous conditioned response is developed when the CS and the US are coincident or when the onset of the CS precedes the onset of the US by an amount of time just sufficient for the CR to occur. Exact simultaneity makes it impossible to follow the course of conditioning over each trial since there is no way to distinguish between the CR and the UR. If occasionally the CS is presented alone, the CR can be measured—but then these trials are extinction trials and interfere with conditioning. Since the acquisition process cannot be measured precisely in the simultaneous situation, it is standard procedure for the onset of the CS to precede the onset of the US and for the CR to be considered a simultaneous CR. The length of the interval between the onset of the CS and onset of the US that defines the simultaneous CR depends on the latency of the UR. For very fast striated-muscle responses, this interval ranges from a quarter of a second up to several seconds. For slow, or long-latency, responses, such as those of smooth muscle and glands, the interval varies from a few seconds up to thirty or more seconds.

Delayed conditioning. With the delayed conditioned response the interval between the onset of the CS and the onset of the US is longer than it is for the simultaneous CR, and the delayed CR also has a longer latency. Delayed CRs are subclassified into short delay and long delay CRs, depending upon the interval between onset of the CS and onset of the US.

Trace conditioning. The trace conditioned response is very similar to the delayed CR. The time relations for onset of the CS and onset of the US are identical. The time relations differ only with respect to the termination of the CS. For delayed conditioning, the CS overlaps the US and terminates either with it or some time after its onset. In trace conditioning the CS lasts as long as a CS in simultaneous conditioning, but it terminates a considerable time before the onset of the US. The trace CR has the same latency as the delayed CR, but because of the short duration of the CS it occurs in the time interval between the termination of the CS and the onset of the US. Since it is assumed in classical conditioning that no response occurs in the absence of a stimulus, it is assumed in this situation that there is a trace of the CS to which the CR is made.

Temporal conditioning. With the temporal conditioned response the US is presented alone at a constant rate. The time interval between successive presentations of the US functions as a CS. The CR

occurs just prior to the time at which the US is to be presented.

Backward conditioning. For the backward conditioned response, onset of the CS occurs after termination of the US and the UR. The CR occurs, of course, to the CS, after the prior occurrence of the US and the UR.

Pseudo conditioning. The pseudo conditioned response occurs without any impaired training trials of the CS and the US. First the US is presented alone for a series of trials. Then, after a short interval of time, the CS is presented alone. If a response similar to the UR occurs to the CS, it is called a pseudo conditioned response.

Effects of temporal variations. The simultaneous CR is acquired most rapidly and with the greatest ease. The first CR may occur on the second or third trial. Delayed and trace CRs are acquired with about equal difficulty if the time between the onset of the CS and that of the US is equal for both. Both are more difficult to establish than the simultaneous CR. For simultaneous, delayed, and trace conditioning the difficulty of conditioning increases as the time between the onset of the CS and that of the US increases. With long delay or long trace conditioning it is impossible to develop a CR unless a simultaneous CR is established first and training trials are then arranged in which the time interval between onset of the CS and onset of the US is gradually increased.

The temporal CR for short intervals of time is more readily established than the simultaneous CR. It may be acquired even when the interval between presentations of the US is as great as thirty minutes. It has not been studied extensively, but because it can be so easily acquired in standard simultaneous conditioning, it is necessary to vary the intervals between trials in a random sequence in order to prevent the occurrence of temporal conditioning.

The backward CR is more difficult to establish than are forward CRs. The difficulty of backward conditioning increases as the interval between termination of the US and onset of the CS increases. The range over which this relation holds is small, since there is no evidence of backward conditioning for the longer time intervals between the onset of the US and the onset of the CS that are possible in delayed or trace forward conditioning.

Pseudo conditioning appears to depend upon the use of a very-high-intensity US that produces a large-magnitude, diffuse, emotional UR. The pseudo CR is neither as readily established nor as stable as a CR based upon equivalent practice with simultaneous conditioning procedures. Pseudo conditioning may be treated as a variant of backward

conditioning, since presentation of the US precedes presentation of the CS. The efficiency of the method is low.

Other factors affecting conditioning. The study of other variables that affect the rate or speed of acquisition has been conducted primarily with simultaneous CRs. However, what evidence there is suggests that the effects of these variables on other types of CRs are similar. Distribution of practice, magnitude of the US, deprivation condition of the organism, physiological condition, neural condition, intensity of the CS, and the number of trials are independent variables that are well established as relating to acquisition.

Distributed versus massed practice. Some degree of distribution of practice provides the most rapid conditioning. The particular optimal distribution depends upon other variables, such as time relations, nature of the US and CS, and nature of the organism. The results universally show massed practice to be inferior to some form of distributed practice in speed of conditioning.

Magnitude of the unconditioned stimulus. Speed of conditioning increases with the magnitude of the US up to a point and thereafter declines with further increases in the magnitude of the US. This has been well established for CRs for which the US is food or electric shock.

Deprivation. The deprivation condition of the organism interacts with the magnitude of the US when the US is food. With very large magnitudes of US and fairly low degrees of deprivation, after only a few conditioning trials the subject may have received its total daily intake and become satiated. When the US is held constant at relatively small magnitudes and the period of deprivation increases, speed or amount of acquisition increases up to a point and then declines with further increase. This relation holds separately for food and for water, but there is probably an interaction between the two.

Deprivation is sometimes treated as a particular physiological condition, but physiological condition usually refers to endocrinological, biochemical, or drug conditions, and the effects of these on conditioning are complex.

Neural conditions. The effects of neural conditions are studied through application of the CS and US at different levels of the nervous system or through the use of conditioning procedures on organisms when varying levels of the nervous system are rendered functionless. Conditioning is possible if the CS is electrical stimulation of the sensory cortex or of the sensory tracts in the spinal cord. There is much evidence that conditioning will not occur if the US is direct stimulation of the motor

cortex. The decorticate animal can be conditioned, but the weight of evidence is against the possibility of conditioning the spinal animal.

Stimulus intensity and complexity. Conditioning increases in rate and magnitude as the CS is increased in intensity from the stimulus threshold to the middle range of intensity but not to greater intensities. Conditioning at very high CS intensities has not been tested. Conditioning occurs at a greater magnitude and faster rate with compound CSs than with any one of the single component stimuli, whether the CSs are from the same or from different sense modalities. Variation in the characteristics of CSs makes it possible to study sensory thresholds and discriminations by conditioning procedures.

Transfer. Many instances of positive and negative transfer have been found in studies of classical conditioning. Transfer is usually positive when it is measured as a difference between performances under conditions that involve acquisition procedures. It is most often negative when it is measured as a difference between performance at a terminal level of acquisition and a subsequent performance that results from alteration of some variable present during acquisition. Positive transfer occurs for any subsequent CR elicited by a new CS, by a new US, or by both at the same time. The only instances of negative transfer under the above conditions occur when the UR and CR for the second treatment are the reverse of or are incompatible with those of the first conditioning treatment.

Stimulus generalization, response generalization, and incentive generalization are forms of positive transfer. Stimulus generalization refers to the occurrence of the CR to stimuli similar to the CS in the absence of specific training with those stimuli. Stimulus generalization declines as the degree of similarity along a given dimension (such as frequency of a tone in cycles per second) decreases. The form of stimulus-generalization gradients is not known because of serious technical difficulties in measuring stimulus generalization. Cross-modal stimulus generalization occurs only rarely. Response generalization can be studied only in limited fashion, such as from right to left side of body, but may also involve opposing responses when the CR is prevented from occurring. Incentive generalization refers to positive transfer of a CR that occurs following variation in the US, such as in the kind of food or in the frequency or locus of application of electric shock.

Extinction. The most striking transfer phenomenon is experimental extinction. This form of negative transfer occurs when, after acquisition,

the US is omitted and the CS is presented alone under the same schedule as that used during acquisition. There is a progressive decrement in the magnitude and frequency of occurrence of the CR to the zero level. This phenomenon has led to a conception of reinforcement of the CR by the US. Empirical nonreinforcement refers to nothing more than the decrement of conditioning when the US is absent from the training procedure, and empirical reinforcement refers to nothing more than the original acquisition of the CR when the US is present in the training procedure and the reinstatement of the CR by reintroduction of the US following extinction. The theoretical views of reinforcement are many, and much of the study of extinction has been directed toward discovery of the reinforcement functions of the US.

With classical conditioning, there appears to be a positive relation between strength of conditioning and resistance to experimental extinction. The greater the amount of conditioning training and the larger the measures of CR magnitude, the greater the resistance to extinction. Any variable that increases the strength of a CR also increases its resistance to extinction. As the degree of extinction training is increased, the amount of training required to re-establish the CR is increased. There is even continued "silent" extinction beyond the zero level of CR: a greater amount of conditioning training is required to re-establish the CR than that required when just the zero extinction level is attained. If there is successive alternation of conditioning and extinction, each reversal requires fewer training trials, until a single trial of either the conditioning or the extinction procedure is sufficient to provide consistent response or response failure to the CS. Speed of extinction is greater for massed extinction trials than it is for distributed extinction trials. Extinction of a CR to one CS will increase the rate of extinction of the CR to a second CS that has not been given extinction training. This is called secondary extinction and is evidence of a generalization of extinction. Delay, trace, and pseudo CRs show more rapid extinction than do simultaneous CRs.

Although reintroduction of the US to the training procedure is the most efficient way to reverse experimental extinction, there are three other procedures that will also produce reversal. If the subject is removed from the experimental room at the time a zero level of extinction has been reached and is returned at a later time, the CS will evoke a CR. This recovery of the conditioned response is called spontaneous recovery. However, with sufficient extinction training there is no spontaneous recovery.

It is possible also to produce recovery of conditioning following extinction by presenting the US alone for a few trials. The CR will then be evoked by the CS presented alone.

Recovery of the CR following experimental extinction may also be produced by disinhibition. This occurs when a novel stimulus is presented in the laboratory at the termination of an extinction series. Disinhibition is a temporary phenomenon, and its magnitude is a function of the extent of extinction and the intensity of the disinhibiting stimulus.

Retention. The retention of classical CRs has received little study. What evidence there is indicates very high degrees of retention in animals who have experienced no conditioning for several years.

INSTRUMENTAL LEARNING

The concept of instrumental learning is a powerful one, primarily because it assists psychologists in their goals of predicting and controlling, or modifying, behavior. The concept is based on an empirically derived functional relationship between the probability of a response and the previous consequences of that response: while battles between theoreticians have not yet been fully resolved, it is generally useful to consider that the probability of a response to a stimulus situation is particularly likely to be strengthened if the response is followed

by what may loosely be called a satisfying state of affairs.

This presentation will be chiefly concerned with applications and implications of instrumental, or operant, learning that may be of more general interest to social scientists; the technical aspects are covered elsewhere [see LEARNING, *article on REINFORCEMENT*].

Adherents of this position have maintained that most of the forms of behavior exhibited by infra-human animals can be effectively analyzed in instrumental terms. A dog approaches when its name is called, horses respond to signals from their riders, cats "know" where to go for food, and cattle avoid an electrified fence, all because of the consequences of previous relevant behavior. Applying the techniques of instrumental conditioning in laboratory settings, experimental psychologists have succeeded in eliciting behavior of great complexity. B. F. Skinner has trained pigeons to engage in behavior that strikingly resembles table tennis. He and his colleagues have also, by reinforcing aggressive behavior, converted usually placid birds into "vicious" killers. The familiar reverse procedure, taming, is also accomplished by instrumental conditioning. Discriminations between colors, shapes, tones, and so forth, can be taught by differential application of reinforcements. For example, an animal can readily be trained to approach a green disc when a low-pitched tone is presented and to approach a red disc in response to a tone of higher frequency. A procedure as simple as this provides a most reliable means of ascertaining sensory capacities of animals. If, say, a food-deprived rat is given food whenever it presses a blue lever but is given no reinforcement when it presses a yellow lever of equal brightness, then equal rates of pressing the two levers would lead us to conclude that the animal cannot distinguish between the two colors. For the sake of simplicity this example has ignored both the possibility that in this instance reinforcement is not effective and the important finding that the kinesthetic and other stimulation resulting from a lever press may itself be reinforcing; recent studies indicate that almost any form of nonnoxious stimulation may possess, under certain specifiable conditions, extremely important reinforcing properties. [See LEARNING, *article on DISCRIMINATION LEARNING*.]

In terms of potential for generalization, few consequences of the learning process are more influential than what Harry F. Harlow (1949) has called "learning to learn." A monkey that has learned to make a particular discriminative response in a particular stimulus situation (e.g., to the "odd" stimulus in a three-stimulus array) has

apparently learned not only that a particular response is rewarded in this situation but also that situations may have embedded in them stimulus properties which, if reacted to appropriately, lead to reinforcement. Thus, if "oddness" ceases to be relevant or reinforcing in this or other situations, a new principle will be sought (e.g., the largest object or the object on the far left of the array). Furthermore, this principle will be discovered far more readily if the animal has previously learned the value of learning.

There is good reason to believe that even some of the most "basic" forms of animal behavior are acquired through and maintained by instrumental conditioning. Copulation, for example, at least in those mammalian species in which it has been carefully studied, is apparently a product of learning. Rhesus monkeys without previous sexual experience have been observed to engage in considerable trial and error—males mounting males, and so on—before arriving at the usual preference for heterosexual intercourse. It is clear that "normal" sexual behavior becomes preferred simply because, for anatomical reasons, it is most likely to be reinforced. Statistically deviant forms of sexuality can be explained in exactly the same way: homosexual or autoerotic activity will tend to be repeated to the extent that it has been positively reinforced. A critical period for learning may exist: learning during a particular portion of the animal's life may be more influential than learning that takes place either earlier or later. Such a possibility would seem to hold greater promise for future research than speculations about the "mental health" of the deviant animals. [See IMPRINTING; SEXUAL BEHAVIOR.]

In a similar vein is the finding by Melzack and Scott (1957) that escaping from pain is a function of particular stimulus dimensions present early in life. It is apparently no longer safe to assume that if a stimulus-response bond is of sufficient biological importance, it is genetically transmitted. [See PAIN.]

As a final example of operant conditioning in infrahuman animals, let us consider what has been called "neurotic" behavior. After an animal has learned that a particular response (e.g., turning left in a T maze) is followed by positively reinforcing stimulation, the experimenter arranges for a strong electric shock, or other negative reinforcer, to be contingent upon the same response. If the experimenter has skillfully controlled his variables, he will have induced conflict. The frustrated animal will display fairly stereotyped behavior: going round in circles, "freezing," or showing other signs of acute and stressful indecision. Even if the shock apparatus is disconnected, the animal will continue

to exhibit this behavior (which presumably serves to reduce anxiety) and may even starve to death unless "therapeutic" measures are taken. It is the compulsive self-destructive nature of the behavior and its origin in conflict that may justify the designation of "neurotic." Generalization to the human level must, of course, be undertaken with great caution. It should be noted that neurotic behavior can also be elicited by classical procedures. [See CONFLICT, article on PSYCHOLOGICAL ASPECTS.]

Instrumental conditioning in humans

B. F. Skinner chose to give to his seminal 1938 book the general title *The Behavior of Organisms*. No new principles, he suggests, need be invoked in order to study human behavior. There is good reason to believe that the human equivalents of the types of behavior described above are also attained, or at least maintained, by means of operant conditioning. Thus, for example, while a definitive experiment will probably never be conducted, it seems reasonable to assume that all forms of sexual behavior are learned by trial and error, by imitation, or by instruction. And both the tendency to imitate and the tendency to follow instructions can themselves be understood as functions of the organism's reinforcement history [see IMITATION].

Language. Perhaps the most important human skill from the standpoint of psychology is language. The initial babblings of the infant are random or semirandom; some sounds, like "ma," are easier to produce than others and will therefore be emitted at a relatively higher base rate. These babblings are differentially reinforced. Differential reinforcement simply means, in this case, that the mother—or other socializing agent—will find certain sounds more reinforcing than others and will behave in such a way as to increase the frequency of these sounds. "Ma," as a response, is strengthened; "ka" and "la" are not. The infant next learns that "ma" is reinforced only under certain conditions. Under other conditions (e.g., when only the father is present), "ma" is either ignored or is negatively reinforced. More complicated utterances can be built up in similar fashion. Thus, while the development of a repertoire of sounds and sound combinations that serve as responses to specific external or internal stimulus situations may be a prodigious feat, it is not a particularly mysterious one (Skinner 1957). Not all language is learned in this rather inefficient fashion. Many utterances result from imitation or from intentional instruction.

Recent experiments have revealed that the verbal behavior of adults can likewise be manipulated. Rates of emission, particular sounds, parts of

speech, sentence length, and content are responsive to operant-conditioning procedures in which a smile or a nod provides quite effective reinforcement (see, for example, Portnoy & Salzinger 1964). It might also be pointed out here that operant conditioning is now being used by Lilly (1963) in an effort to teach bottle-nose dolphins to use the English language "intelligently." [See LANGUAGE, article on LANGUAGE DEVELOPMENT.]

Creativity. Another important kind of activity, creativity, is also susceptible to analysis in these terms. Here the key psychological, as distinguished from sociological, variable is novelty of response to a stimulus situation. Numerous studies (e.g., Maltzman et al. 1960) have demonstrated that the individual will learn to make novel responses if he is rewarded for doing so. A "motive" for originality is thus instilled just as readily as the "motive" for conformity is instilled in most of our educational institutions. The learned tendency to produce "original" responses, combined with the learned tendency to view one's productions critically, may be enough to explain even the highest achievements of human creativity. The fact that computer-type machines can be programmed to "create" music in a large variety of styles points in the same direction. [See CONFORMITY; CREATIVITY.]

Emotional behavior. Operant conditioning also provides a useful framework for studying those most complicated psychological processes, the emotions. Whether they are subjective states or physiological events, or both, emotions may be viewed as (a) responses to antecedent stimuli and (b) stimuli for consequent responses. As responses, emotions are learnable. It is extremely doubtful that the newborn infant has any emotions at all; he almost definitely is not afraid of the dark, or of falling, or of snakes; he does not love his mother, nor does he feel inferior. How are these emotions learned? It appears that no new principles need be invoked. A child observing his mother's frightened reactions to a thunderstorm may exercise his acquired tendency to imitate by manifesting similar signs of fright. These signs are reinforced by maternal solicitude. Studies indicate high correlations between the fears of children and of their parents (Hagman 1932).

As an extended hypothetical example, consider what is generally called love. The child may learn that the words "I love you" are often followed by more tangible rewards and that his own manifestations of "loving" behavior are followed by rewards from people in his environment. Consequently he may learn to seek out circumstances in which it is appropriate for such kinds of behavior to occur. He wants to love and be loved. The rewards of

establishing a love relationship, which go far beyond the food and tactile stimulation that probably served as initial reinforcement, may include temporary freedom from corporal punishment, victory in a sibling rivalry, or erotic stimulation. With such a multitude of possible reinforcements, the child may readily learn those forms of behavior that elicit "loving" behavior from the people in his environment. And one particularly effective method for achieving this is to engage in "loving" behavior oneself. But since the well-socialized child has also probably learned that there are negative reinforcements for deceptive behavior, he must get himself to actually "feel" the emotion he is expressing. This necessary internal state is conditionable, but a classical conditioning model is probably more useful here than the operant model. [See **AFFECTION**; **EMOTION**; **MORAL DEVELOPMENT**; **PERSONALITY**, article on **PERSONALITY DEVELOPMENT**.]

Religiosity. One's religious convictions may likewise be regarded as nothing more than a complex set of learned responses to a complex set of stimuli. The objection that man is born with a knowledge of and reverence for God receives its strongest rebuttal from the practices of the major religions, whose emphasis on Sunday school and other forms of religious instruction seems at odds with such concepts as revelation or innate knowledge. The combination of formal religious training, informal parental inculcation (e.g., answering "God did it" to difficult questions in the natural sciences), and ubiquitous social pressures (e.g., the motto "In God We Trust" on U.S. currency) makes clear why so many children engage in religious behavior. Whether the mediator in such cases is the learned motive to conform or the learned motive to imitate, religious utterances and other religious activities tend to be positively reinforced. The intense emotionality that so often accompanies or defines the "religious experience" may result from the capacity of religion to satisfy such needs as dependency, affiliation, and (perhaps) erotic gratification, needs that may themselves be products of instrumental learning. Thus, to the extent that religiosity is inferred from behavior, principles of conditioning appear to be sufficient for a complete explanation. [See **RELIGION**.]

Mental illness. As a final example of the widespread applicability of these principles, we may consider those forms of behavior that characterize "mental illness." It is possible to regard the disordered or undesired behavior simply as a set of responses that have become progressively stronger because of their reinforcing consequences. This formulation holds true even if the behavior (nail-biting, cigarette smoking, destructive interpersonal

relationships, self-degrading activities) appears to have negative consequences. The "reward" in such cases may be temporary relief from anxiety, satisfaction of abnormally strong learned needs to conform or not conform, to confirm a self concept, and so on. There may be a wide gap in complexity between a rat that makes the correct choice in a T maze and an accident-prone human, but it is possible to understand the behavior of both animals in terms of the same principles. [See **MENTAL DISORDERS**; **NEUROSIS**.]

Practical applications

In most sciences, including psychology, the goals of prediction and control, or modification, are inextricably related. While the foregoing paragraphs have emphasized the prediction of responses, the following examples refer specifically to the possibility of response modification or control.

Programmed instruction. The widespread adoption of "teaching machines" and other programmed instructional devices in schools all over the world attests to the ability of operant methods to establish the repertoire of stimulus-response bonds deemed necessary by society. Instead of the primary reinforcement of a pellet of food, so often used to control or shape the behavior of infrahuman animals, it has been found that such secondary reinforcers as "the feeling of success" are extremely effective for human students of all ages. There is nothing mysterious about these secondary reinforcers; their emergence can be predicted—or arranged—by virtue of their frequent association with primary rewards. So long as teacher shortages exist, programmed instructional devices will continue to be useful adjuncts to more conventional pedagogic techniques. But these devices are of far more than ancillary value. They provide advantages that are uniquely their own. Each student is permitted to proceed at his own rate and thus avoids either the boredom or the frustration that may result from the single-level approach so often necessary in crowded classrooms. Furthermore, the use of programmed materials largely does away with extrinsic rewards, such as grades and teacher-approval, by relying primarily on the reinforcing nature of the learning process itself. While many of their potentialities remain to be developed, it is difficult to conceive of any academic subject matter that cannot be taught, and taught effectively, by means of these methods. [See **LEARNING**, article on **PROGRAMMED LEARNING**.]

Behavior therapy. Principles of operant conditioning have also been found to be extremely useful in the modification of undesirable behavior. The behavior in question, whether it involves an

isolated S-R connection (e.g., fear-responses to heights) or a complex pattern of behavioral tendencies from which some clinicians infer "neurosis" or "psychosis," can be altered by extinguishing the undesired response while building up a desired response (or set of responses) to the same stimuli. For example, homosexuality—a form of behavior that is notoriously resistant to traditional varieties of psychotherapy—often responds quite favorably to what is called behavior therapy (see, for example, Feldman & MacCulloch 1964). Procedures differ widely, but the following outline of treatment may be of illustrative value. The "patient" (a term which is particularly inappropriate in this context) is requested by the therapist to have a homosexual fantasy. When he signals that the fantasy has reached a peak of excitement, the individual receives a painful electric shock. This procedure is repeated over several sessions, with the result that in subsequent interviews, when it is clear to the patient that shock will not occur, he reports that homosexual thoughts and behaviors are gradually being extinguished. During the extinction process, heterosexual motives and activities are strengthened by means of familiar techniques of reinforcement. Early in the treatment, for example, the individual is directed to masturbate while engaging in heterosexual fantasies; before very long, an association develops between having an orgasm and visualizing a partner of the opposite sex. Within one year most individuals exposed to this form of treatment are behaving in ways acceptable to society and to themselves outside the therapist's office. New forms of undesirable behavior do not appear, and the proportion of "relapses" is far smaller than that encountered in other forms of treatment. [See MENTAL DISORDERS, TREATMENT OF, *article on* BEHAVIOR THERAPY; SEXUAL BEHAVIOR, *article on* HOMOSEXUALITY; see also Feldman & MacCulloch 1964.]

Obviously, behavior therapy is not simply symptom removal. Starting with the premises that the undesired behavior has been learned and that whatever has been learned can be unlearned, the method proceeds to instill new learnings as efficiently as possible. As a by-product of this counterconditioning, we may expect a reduction in the anxiety engendered by the behavior in question. This reduction, as measured, for example, by the galvanic skin reflex, will, in turn, tend to lower the frequency of pathological behavior. Alternatively the therapist may choose to attack the anxiety more directly by viewing it as a learned response to specifiable interpersonal or other stimuli. [See ANXIETY; PERSONALITY, *article on* THE FIELD.]

There appears to be no qualitative difference

between the treatment of a simple self-destructive habit and of the most complex of neurotic constellations. Although some critics might accuse them of unjustified reductionism, proponents of behavior therapy would allege that the more conventional methods of treatment take longer and have a lower success rate because the necessary learning process is managed inexpertly, being incorrectly regarded as little more than an epiphenomenon of insight, catharsis, and so on.

The apparent therapeutic effectiveness of Skinnerian methods should not blind the reader to the equally stimulating applications of Pavlovian methodology to behavior therapy. The cautionary note should also be added that the number of individuals, the number of conditions treated, and the duration of follow-up studies are not yet sufficient to justify unreserved acceptance of the new methodology. Still, unlike certain other recent innovations in therapy, the use of conditioning is firmly based on a mass of quite unequivocal laboratory data. [See MENTAL DISORDERS, TREATMENT OF.]

Implications

As has been indicated, the principles and practices of instrumental conditioning provide useful tools for the prediction and control of behavior. This practical utility leads to a consideration of a number of quite crucial questions.

First, can a science of psychology exist entirely on the basis of prediction and control, without regard to the task of *understanding* behavior? The question virtually answers itself if the goals of understanding are made explicit. Although the wish to understand is, for some, based largely on intellectual curiosity rather than on the desire for practical applications, there are only two ways that one can persuasively confirm, test, or demonstrate understanding: by predicting or by controlling the phenomena he claims to understand. Furthermore, some psychologists wish to understand primarily because they wish to predict and control. It might also be pointed out here that the individual who wishes to apply psychological principles to his own betterment can do so by means of, and perhaps only by means of, that intelligent arrangement of stimulus-response contingencies called self-control. Clearly, the specification of empirical regularities in the occurrences of stimuli and responses eliminates the need for prior "understanding." The thoroughgoing adherent of the instrumental point of view might also claim that explanations of behavior in terms of the functioning of the central nervous system are likewise unnecessary.

Second, are there any forms of behavior that do not make sense within the framework of instru-

mental learning? Some writers have argued that behavior which is very complex requires a more complicated explanatory model; but complex behavior—including behavior that involves language—yields readily to instrumental analysis. Such analysis of a phenomenon is not, of course, logically identical to a valid causal explanation of it. Some also maintain that there are forms of complex behavior (referred to as “instinctive”) that are genetically determined, but the realm of instinct seems to dwindle as more and more alleged instances yield to analysis in terms of prenatal or early postnatal conditioning. Certainly at the human level the concept of instinct seems no longer useful. On the other hand, there is no need to deny the existence of genetically transmitted unconditioned reflexes. [See GENETICS, article on GENETICS AND BEHAVIOR; INSTINCT.]

Perhaps the best objection to what might be called instrumental imperialism is that many kinds of behavior fit more readily into the framework of classical, rather than operant, conditioning. But it may be that these two categories are not really distinct from each other. To give a somewhat oversimplified example, Pavlov's dogs may have learned to salivate to the initially neutral stimulus because the response of salivation was “paid off” by the presentation of food.

A final consideration has to do with the ancient problem of free will versus determinism. If behavior is nothing but responses to stimuli, and if the stimuli determine the responses, then the concept of free will ceases to be necessary. The fact that different people may respond differently to the same stimulus is, of course, beside the point. The stimulus may not be the “same” at all, being contingent upon receptors, thresholds, and previous conditioning. And even if the stimuli are viewed as identical, response differences would be explicable by virtue of individual differences in reinforcement histories or physical abilities.

Because of the number and the complexity of the determining variables, some behavior may be, practically speaking, “unpredictable.” But this practical limitation in no way justifies an explanation of such acts in terms of free will. Analogously, the result of a coin flip, while usually attributed to “chance,” is the inevitable outcome of a set of variables: air currents, the force of the flip, the distance the coin is permitted to drop, and so on. While these variables can be ascertained only with great difficulty, we do not conclude that the coin has manifested free will. The same line of reasoning may be raised against those who invoke the physicists' principle of indeterminacy in support of the free-will position.

In short, as the instruments, methods, and concepts in the science of psychology become increasingly sophisticated, the number of unpredictable and uncontrollable human acts appears to be shrinking proportionately. The widespread application of conditioning procedures is not without its dangers. But the possible abuses of this powerful tool should not obscure the recognition of its potential advantages. It does not seem unrealistically optimistic to view instrumental conditioning as a way, perhaps the way, to elicit from human beings those forms of creative, satisfying, and socially useful behavior that the less-systematic educational methods have so conspicuously failed to obtain.

Instrumental conditioning is by no means a new method of behavioral development. Indeed, if its principles are valid, they were operating long before they were formulated. But the recent advances that have been reviewed herein suggest that these principles will play an increasingly pivotal role in twentieth-century psychology.

IV REINFORCEMENT

The principle of reinforcement is not new. One form of that principle, the law of effect, dates back to Thorndike (1898-1901), who was one of the

first systematic experimenters to observe that the development and maintenance of new instrumental performances are closely controlled by their environmental consequences. Thorndike theorized that an organism's behavior was "stamped in" when it was followed by a satisfying state of affairs. By a satisfying state of affairs, Thorndike meant a condition that the animal did nothing to avoid, and whose maintenance and renewal the animal sought. Although our language has developed in the interest of greater scientific objectivity, and our experimental methods have progressed in the direction of greater precision and analytical prowess, Thorndike's early observations on trial-and-error learning represent the foundations of modern effect, or reinforcement, theory.

In contrast to the trial-and-error, or instrumental, learning studied by Thorndike, Pavlov (1927) worked with classical conditioning procedures. Perhaps the best known example of Pavlov's work is salivary conditioning. A stimulus which does not initially elicit salivation (the conditioned stimulus: a bell or metronome, for example) is presented in close temporal conjunction with a substance that does elicit salivation when placed in the mouth (the unconditioned stimulus: food powder or dilute acid, for example). After several paired presentations of the conditioned and unconditioned stimuli—provided sufficient attention is given to the details of the conditioning procedure—the conditioned stimulus gains the power to elicit salivation as a conditioned response. Because the development and maintenance of the conditioned response are closely dependent upon presentation of the unconditioned stimulus, the latter has been called a reinforcing stimulus.

Generalizing from the above considerations, it can be said that both instrumental, or Thorndikean, and classical, or Pavlovian, reinforcers may be looked upon as critical events in a learning episode. Just as the occurrence of reinforcement "strengthens" behavior, so the omission of reinforcement "weakens" behavior. In both instrumental and classical conditioning, the elimination of behavior by removing the reinforcer responsible for its maintenance is called *extinction*. Space does not permit a detailed comparison between instrumental and classical conditioning procedures. The reader is referred to Kimble's revision of Hilgard and Marquis' *Conditioning and Learning* (1940).

While this discussion has stressed the importance of reinforcement in learned behavior, it should be noted that not all psychologists agree on this point. E. R. Guthrie (1935), for example, developed a theoretical system in which learning does not depend on reinforcement. Although Guthrie

agreed with Thorndike that learning consists of the bonding or conditioning of responses to stimuli, Guthrie maintained that simple temporal contiguity of response and stimulus is sufficient. Thorndike, it will be recalled, stated that reinforcement, that is, the satisfying state of affairs, was necessary in addition to stimulus response contiguity. Perhaps the most extensive stimulus-response reinforcement theory was developed by C. I. Hull (1943). The similarities and differences among the various theories of learning constitute a study in themselves—Hilgard's *Theories of Learning* (Hilgard & Bower 1948) should be consulted as a general reference. An indication of the type of research evolving from a theoretical concern with the nature of reinforcement is provided by Bunney and Teevan's *Reinforcement* (1961), a collection of original papers—some classics—by prominent experimentalists.

Instrumental or operant behavior

Particularly important in the development of knowledge regarding the dynamics of reinforcement has been the work of B. F. Skinner (1938; 1953) and his colleagues. Skinner has adopted a nontheoretical, descriptive approach in his analysis of behavior, and the results of his work have had great practical and systematic significance. The methodology characteristic of Skinner's work has been analyzed and discussed by Sidman (1960) in his book *Tactics of Scientific Research*.

Instrumental, or operant, behavior may be defined as behavior that is under the control of its environmental consequences. Opening a door, walking across the street, speaking, etc., are examples of operant behaviors. When the consequence of a behavior serves to increase the frequency or probability of occurrence of the behavior, we refer to the consequence as *reinforcement*. *Positive reinforcement* involves the onset of some stimulus as the reinforcing consequence; *negative reinforcement* involves stimulus termination as the reinforcing consequence. Negatively reinforcing stimuli are often called *aversive stimuli*; it has been found that the onset of an aversive stimulus contingent upon a behavior will often decrease the probability of occurrence of that behavior. The reinforcement relationships just described are actually quite complex, and no simple statement will adequately summarize all of the detailed facts regarding positive and negative reinforcement. However, types of reinforcers and the ways in which they have been manipulated provide for some of the well-known behavioral paradigms.

Reward training. In reward training a positive reinforcer is contingent upon the occurrence of a

response. Thorndike's experimental situation is a case in point; modern versions of the procedure involve such arbitrarily selected experimental behaviors as lever pressing, running in mazes and alleys, turning a wheel, jumping a gap, and, in humans, verbal behavior. Typical reinforcers that have been employed are food and water, for an animal appropriately deprived; the opportunity to engage in sexual activity or to explore a novel environment, money, praise, etc., have been used with humans.

Escape training. Negative reinforcement involves the termination of an aversive stimulus. The behavior which terminates that stimulus is called escape behavior. Arbitrarily selected behaviors like those mentioned above have been used to study the properties of negative reinforcement. The most frequently used negative reinforcer has been electric shock, although reproof, social isolation, etc., have been used with humans.

Avoidance training. While an escape-training paradigm involves the presentation of the aversive stimulus independent of the organism's behavior, a paradigm can be arranged in which some arbitrary response postpones or avoids the delivery of the aversive stimulus. Any response which does so is an avoidance response. Often a warning stimulus, such as a light or a buzzer, precedes by some predetermined period of time the scheduled occurrence of the aversive stimulus. In this arrangement, called discriminated avoidance, a response occurring between the onset of the warning stimulus and the scheduled onset of the aversive stimulus is the avoidance response. Typically, a response occurring during that interval terminates the warning stimulus and results in the avoidance of the aversive stimulus. Sidman (1953) has carefully studied an avoidance procedure, called nondiscriminated avoidance, in which no warning stimulus occurs. Instead, the aversive stimulus, such as electric shock, is scheduled to occur on a purely temporal basis. A response recycles a timer, and the shock is postponed. Ordinarily, more than one temporal interval is involved in this kind of experiment.

Punishment training. Punishment training involves the onset of an aversive stimulus contingent upon the occurrence of a response. An effective procedure for studying punishment has been employed by Azrin and is described by Azrin and Holtz (1965). Animals are trained to respond through the use of positive reinforcement. A punishment is then applied, and the local, transient, and permanent effects of punishment are studied.

This outline is necessarily brief and cannot do justice to the many detailed findings in the control

of behavior through reinforcement contingencies. In order to explore further some of those findings, however, we may consider in more detail the positive reinforcement of operant behavior.

Reinforcement and chaining

Some of the important facts regarding reinforcement can be displayed by considering a laboratory example where a pigeon is trained to step on a treadle in the rear of an experimental chamber, then to peck on an illuminated plastic disk or key on the wall, and, finally, to approach and eat from a grain tray. The first step is the adaptation of a hungry pigeon to the experimental chamber. After the bird is in the chamber for several minutes, the food tray is raised, with the grain illuminated by a small overhead light. The tray is held in place until the bird sees and eats some grain. After the bird has eaten for several seconds, the tray is dropped away, out of reach of the bird, and the light is turned off. The procedure is repeated until the bird responds immediately to the lifting of the tray and the illumination of the grain. By temporally spacing tray presentations, we provide for the extinction of approach behavior when the tray is not in the lifted position.

For the next step, we illuminate the translucent plastic disk on the wall. The pigeon is trained to stay in the vicinity of the disk by means of a procedure known as *successive approximation*. In this procedure each movement of the bird is noted, and as soon as a movement occurs that brings him a little closer to the disk, the grain tray is immediately lifted for a few seconds and the bird is allowed to eat. When the bird is near the disk his finer movements are observed, and, again by successive approximation, we bring his beak closer and closer to the disk until he pecks it. Each closer approximation to the desired response of pecking the disk is immediately followed by, that is, *reinforced* with, access to the grain tray. Next, we darken the disk and permit the pigeon to peck. The grain tray is not lifted. Soon the key is illuminated and a peck is followed by the grain tray's being lifted. Several pecks at the dark disk are allowed, but none of them is reinforced with food. When the disk is illuminated, a peck produces grain. This procedure (that is, *discrimination training*) results in a rapid decrease in the frequency of pecking at the dark disk, with the maintenance of a high probability of pecking at the illuminated disk. In the final step, another example of successive approximation, we start with a dark disk. A movement by the pigeon in the direction of the treadle is immediately followed by illumination of the disk. The pigeon is allowed to peck the disk and eat from the tray. As

before, when he pecks at the dark disk, the grain tray is not lifted. By the illumination of the disk, contingent on some preselected aspect of the bird's behavior, we get him closer and closer to, and finally stepping on, the treadle. The behavior sequence is complete. The pigeon steps on the treadle; the disk is illuminated; the pigeon pecks the disk; the grain tray is immediately raised for a few seconds; the pigeon approaches the tray, and sees and eats the grain.

Paradigm of behavior chain. The behavior chain may be written symbolically, as follows (" $S_x: R_x \longrightarrow$ " indicates the stimulus, S_x , in the presence of which a specified response, R_x , will have a specified effect, that is, \longrightarrow , the production of a new stimulus):

If the behavioral chain in question is "free running," that is, if the bird is permitted to run it through over and over (a recycling chain), we might specify another stimulus event, S_0 . The dropping away of the grain tray, S_0 , is "produced" by (more exactly, correlated with) R_4 . Thus, S_0 becomes the stimulus event in the presence of which the bird emits R_0 , approach to the treadle. The approach response R_0 produces S_1 . Thus the chain is closed, forming a continuous behavioral sequence that might be expected to continue as long as deprivation (motivational) variables are effective, all else being equal.

Conditioned and primary reinforcers. In analyzing the sequence of events that we have just described, it is important to notice that the actual reinforcers maintaining the specific responses are light and sound rather than the ingestion of food. This is the distinction between *conditioned* and *primary* reinforcement. While the primary reinforcement, that is, the ingestion of food, is a necessary condition for maintaining the bird's over-all performance, the conditioned reinforcers are made instantaneously and precisely contingent on the exact form of behavior that we wish to maintain. Virtually all operant behavior is maintained by conditioned reinforcers such as sounds and lights analogous to those described above, rather than directly by primary reinforcers such as food, water, oxygen, etc.

Principles of reinforcement. The preceding demonstration illustrates the following important principles pertinent to the operation of reinforcement:

(1) The strength of the several components

of the response chain—stepping on the treadle, pecking the key, approaching the food tray—is maintained by their immediately reinforcing consequences. This fact can be demonstrated by performing extinction operations within the chain. Suppose we permit the pigeon to step on the treadle; but now, unlike the previous situation, we do not illuminate the disk when the pigeon responds in this way. Since the disk is not illuminated, the pigeon does not peck at it; but ceasing to illuminate the disk also constitutes the removal of conditioned reinforcement for the initial chain link, that is, stepping on the treadle. As a consequence of that removal of reinforcement, we may note first an increase and then certainly a decrease in the dis-

position of the bird to step on the treadle. The chain has been broken at its initial link. As a matter of fact, we could have broken the chain at any of its links by the simple expedient of removing the immediately reinforcing consequences of any of the responses making up the chain.

(2) Experiments of the kind just described demonstrate clearly the essential relationship among the several reinforcers of the chain. Food, the primary reinforcer that occurs at the end of the behavior sequence, is necessary to maintain the entire chain in strength, but each one of the several arbitrary links is closely controlled by the conditioned reinforcer that it immediately produces.

(3) A stimulus such as the illuminated response key serves a double function. Not only is it a reinforcer for the immediately preceding behavior, but it sets the occasion for the next response in the required sequence. Illumination of the key not only reinforces stepping on the treadle, but it also sets the occasion (that is, serves as a *discriminative stimulus*) for which a peck at the key will be reinforced. Implicit in the discriminative control by the illuminated disk is the corollary fact that when the disk is not illuminated, responses to it will have no further effect, the animal cannot progress any further in the chain. Since the animal's behavior is under the specific control of each stimulus element in the chain, it is this discriminative control by each stimulus element in the chain that keeps the sequential emission of the chain going.

(4) The chain is constructed by starting with its final component. After the final component

is securely developed, the next to the final one is added. When this is securely developed, another is added, and so on. In other words, the chain is built in a backward sequence. The reason for this procedure is readily appreciated if we take note of the fact that at the beginning of our training procedure we have at our disposal a single strong reinforcer, namely, the grain. The other events that finally serve as the conditioned link reinforcers are initially neutral and arbitrary events, such as light and sound. In order to establish such stimuli as conditioned reinforcers, it is necessary to associate them with already established reinforcers. Therefore, the compound stimulus, consisting of a flash of light illuminating the grain and the slap of the tray being raised, is established as a reinforcer through its association with the grain. It is thus capable of strengthening and maintaining peck responses on the illuminated disk. Note, however, that the illuminated disk is now correlated with the flash of the feeder light and the sound of the tray. By virtue of this association, the illuminated disk itself becomes a conditioned reinforcer and can be used to strengthen and maintain still an earlier member in the chain. Thus, practical considerations dictate the backward development of the sequence of conditioned reinforcers, and it is this development that makes advisable the backward development of a behavioral chain. A detailed review of positive conditioned reinforcement has been published by Kelleher and Gollub (1962).

Kinds of control through reinforcement

Continuous versus intermittent reinforcement. For many years the typical laboratory experiment involved the *continuous reinforcement* of the criterion response. Continuous reinforcement refers to a schedule of reinforcement in which the behavior in question is reinforced each time it occurs. It is clear that an analysis of behavior restricted to this experimental program can have limited applicability to the affairs of men. Men live in complicated societies. Their behaviors are not reinforced by automatic "grain trays," but are subject rather to the possible whims and fancies of such agencies of society as government bureaus, social groups, religious groups, and, perhaps most important for the day-to-day existence of most of us, other individuals at home, at work, and at play. If there is any outstanding characteristic of people either in groups or as individuals, it is that their behavior is complexly determined. As a consequence of this complex determination, behavior is reinforced on an intermittent basis when individuals interact. For this reason, the general problem of intermittent

reinforcement must occupy a central and crucial place in the experimental analysis of behavior, if the latter is to come to grips with the problems of human performance.

Intermittent reinforcement refers to the case where some of, rather than all, the occurrences of the specified response are followed by a reinforcer. The phrase *schedule of reinforcement* refers to the particular rule by which reinforcement is made contingent upon some occurrence of a response. Broadly speaking, there are two general schemes whereby reinforcers can be related to response emission. Within either of these schemes, not to mention those cases where they are combined, there are literally thousands of different schedules. Many of the simpler ones and some of the more complex ones have been extensively studied in the laboratory using both animal and human subjects.

Interval and ratio schedules. When a rule specifying the contingency between a response and its reinforcement involves the passage of time, we speak of *interval schedules*. For example, we may specify that reinforcement will occur on the first response following a fixed period of elapsed time since the last reinforcement. Such a schedule is referred to as a *fixed interval* schedule of reinforcement. On the other hand, when the contingency involves some number of responses we speak of *ratio schedules*. We may specify that reinforcement will occur following the emission of the n th response since the last reinforcement. This rule, specifying a fixed number of responses, is ordinarily referred to as a *fixed ratio* schedule of reinforcement. These are simple cases, but they exemplify the two broad classifications of response-reinforcement contingencies referred to as "interval" and "ratio" schedules. These two broad classifications of reinforcement contingencies produce behaviors that have markedly different properties.

Characteristics of ratio schedules. Fixed ratio schedules are generally characterized by high rates of response emission. As the reinforcer is made contingent upon successively higher and higher response requirements, sharp breaks in responding ordinarily develop. Initially, these breaks appear following a reinforcement and preceding the next ratio run. Later, when the ratio requirement has reached some relatively high number, breaks may occur at various places during the ratio run. An outstanding characteristic of ratio performance is that the organism is either not responding (pausing) or is responding at a relatively constant rate. If the ratio requirement is increased still further, responding becomes relatively sporadic; we refer to this condition as ratio strain.

It is no secret that a type of gambling machine, the slot machine, is designed in accordance with the principles of ratio behavior. The payoff frequency must be great enough so that the gambling behavior does not show marked strain. On the other hand, the exact ratio contingency must not be defined by the emission of a *fixed* number of responses. If that were the case, we would observe potential gamblers waiting for the other fellow to play until, of course, $N-1$ coins had been fed the machine. Then there would ensue a dash to the machine in order to make the payoff response. Instead, the slot machine is programmed according to a *variable ratio* schedule of reinforcement. In this case, reinforcement is again contingent upon the emission of a number of responses, but the number of responses required differs from reinforcement to reinforcement. A variable ratio schedule of reinforcement is less susceptible to the development of ratio strain. Although very large numbers of response occurrences may be required for some instances of reinforcement, other instances occur after very few responses. Through judicious selection of a sequence of ratio sizes in a variable ratio program, the slot machine may be made to show a consistent profit.

Characteristics of interval schedules. The properties of interval schedules are different from those of ratio schedules. Interval schedules often show intermediate rates of responding. In the fixed interval case mentioned earlier, one frequently observes a relatively smooth transition from a zero rate of responding immediately after a reinforcement to a fairly high rate of responding preceding the next reinforcement. The characteristic shape of the fixed interval, cumulative-response graph is referred to as a *fixed interval scallop*. As in the case of variable ratio reinforcement, we can specify a rule that defines the *variable interval* case. In a variable interval schedule of reinforcement, reinforcement availability is again made contingent upon elapsed time, but, unlike the fixed interval case, the periods of time that must elapse between the reinforcements vary in a random sequence around some selected value. By the careful selection of interval sizes and their exact order of occurrence, one can produce a nearly uniform rate of responding, if one desires to do so. In fact, there have been variable interval response graphs that were so regular, a straightedge would be required to detect deviations from regularity. It can be seen, then, that the schedule of reinforcement, to a considerable extent, serves to control the rate and pattern of response emission. Schedules also serve to determine the characteristics of extinction, when

reinforcements are no longer obtainable. A schedule of continuous reinforcement produces a relatively brief extinction curve, whereas a schedule of intermittent reinforcement may produce a protracted extinction curve characterized by a gradual transition from a high rate of responding to a zero rate after variable interval reinforcement, or gradually increasing periods of no responding punctuated by response bursts at a constant rate after ratio reinforcement.

Motivation. Schedules of reinforcement, to a large extent, account for some of the properties of behavior that are often referred to as "motivational." Individuals characterized as highly motivated or "driven" may in fact be individuals who are capable of sustaining high ratio requirements without obvious signs of strain. On the other hand, people who are characterized as lazy or indolent may be, in fact, individuals who are not capable of sustained performance on even a modest ratio requirement. While such characterizations must not be accepted on the basis of face validity, they do have the merit of suggesting methods of changing the behaviors of such individuals. In this way, the research of the animal laboratory can be brought to bear on the problems of human behavior. The reader interested in the details of reinforcement schedules should consult *Schedules of Reinforcement* by Ferster and Skinner (1957). [See DRIVES; MOTIVATION.]

Differentiation of new response forms. It has been seen that schedules of reinforcement can be utilized to control the rate and pattern of response emission. Another major function of reinforcement is to create "new" behavior. By the creation of new behavior, we do not mean the creation of something out of nothing, but rather the transition from one form of behavior into another. There are many examples from the world of human affairs. The powerful and accurate play of the professional golfer is created from the fumbling, awkward movements of the beginner. The changes characterizing such a transition in behavior are not simply quantitative in the sense that a change in response rate is quantitative. The professional golfer does not simply move faster or swing his club more often. Rather, his performance is qualitatively different from that of the beginner. It may be seen that the development of new behavior is often a problem in the acquisition of skills. We have already specified the essential process by which skills are acquired; that is, successive approximation. Once we can specify the form of the final behavior that we desire, we can, starting with almost any arbitrary performance, bring about the

desired behavior by stages. The instructor, teacher, therapist, or any other individual who is concerned with the creation of new behavior in others must be capable of recognizing closer and closer approximations to the desired performance. In addition to recognizing these closer and closer approximations, he must have at his disposal a conditioned reinforcer that may be presented immediately upon the appearance of an acceptable intermediate performance. Verbal reinforcers such as "good" or "now you have it" are often used with humans. Improved control over the immediacy of reinforcement was one of the major considerations in the development of the new and very promising technique of programmed instruction or, as it is often called—with misplaced emphasis on the hardware—"teaching machines."

Differential reinforcement. The critical procedure in the development of new behavior involves a process known as *differential reinforcement*. Differential reinforcement refers to a procedure in which reinforcement is administered upon the occurrence of some behaviors and withheld upon the occurrence of other behaviors. The extremely powerful and precise control that may be gained over behavior through differential reinforcement is responsible for the success of the successive approximation technique. Since reinforcement may be made contingent upon either a qualitative or intensive property of a response, the procedure may be used to change the topographical characteristics of the response or its intensity.

Consider the example of a young child ignored by his parents. In searching for attention, he may emit a wide range of specific behaviors, differing enormously with respect to topography. Any of these behaviors that succeeds in gaining attention from the parents will be strengthened to some extent and become prepotent over the others. Attention is reinforcing. By the process of differential reinforcement, the parents can create a new and strong behavior pattern in the young child. It is no accident that in the practical case the new behavior pattern typically involves some element of aversiveness for the parent. The parent, after all, is a reinforceable organism. Termination of the child's aversive behavior serves to reinforce the parent's behavior, which, as we have noted, may likewise serve to reinforce the behavior of the child. It may be readily appreciated how a vicious feedback system may be developed. In order to gain attention from the parent, the child raises his voice or generally displays some other form of temperamental behavior. Because this behavior is aversive to the parent, the parent terminates it by responding to

the child. The attention thereby shown to the child reinforces the temperamental display. Through a process of adaptation to the aversive properties of the child's behavior, or simply because the parent may not want to "give in" so readily, attention may be withheld on some specific instance of a temperamental display. Since an increase in the intensity of a temperamental display will ordinarily establish a new level of aversiveness, it is likely that the parent will respond to that new level with immediate attention. As a result, a more intense form of the temperamental display is differentially reinforced. The end result of such a feedback system is one that most of us have seen at one time or another. The fundamental mistake made by the parent at the outset is to respond to (that is, reinforce) any form of behavior that has aversive properties for him. By withholding reinforcement under these conditions and responding with attention when some form of nonaversive behavior is emitted by the child, the whole problem can be avoided. On the other hand, starting with a child who has already developed in strength some form of aversive behavior, the principle of differential reinforcement may be used in order to short-circuit the development of the feedback system. Simple withholding of reinforcement on all temperamental displays by the child will produce eventual extinction of that form of behavior. Perhaps a more positive approach would be to combine extinction of intense forms of temperamental display with deliberate reinforcement of less and less intense exhibitions by the child. Ultimately, the child will have learned that attention, and hence satisfaction of his needs, will be forthcoming only when his request is stated moderately.

The dynamic properties of reinforcement

We have stressed the importance of immediacy in the effective use of reinforcement. A reinforcement that is delayed after the occurrence of the criterion behavior will ordinarily occur in close temporal proximity to some other behavior. Although there might be some tendency for the criterion behavior to be strengthened, maximal strengthening will occur with respect to the intervening behavior.

Superstition and uncontingent reinforcement. If the intervening behavior that is maximally strengthened is incompatible with the criterion behavior, we might, in fact, note a decrease in the strength of the criterion behavior. Perhaps the most dramatic example of the effect of uncontingent reinforcement is the well-known "superstition" experiment (Skinner 1948).

A hungry pigeon is placed in an experimental chamber, and the grain tray is operated at fairly frequent intervals, but independent of the animal's behavior. After a period of time, we note the development of some rather strong behavioral patterns during the intervals between reinforcement. Frequently, these behavior patterns appear quite bizarre. The pigeon, for example, may hop about on one leg while fluttering a wing, or the bird may dance furiously from one side of the box to the other while stretching its neck. The important point is that these behaviors have developed as a function of the uncontingent reinforcement: *Simply because the reinforcement has not been made experimentally contingent upon some specified response does not mean that the reinforcement was without effect.* In fact, what will always happen is the strengthening, by the reinforcement, of some chance behavior. By the process of differential reinforcement, the behavior that is accidentally reinforced may show some slow drift in topography. After a period of time, we actually might note a completely different topography from that which we observed earlier. As a general principle, we may state that the more immediate the reinforcement is with respect to the criterion response, the more highly stereotyped the criterion response is likely to be. Less immediate reinforcement will produce somewhat looser control, with a noticeable tendency for the criterion response to change in time. We may, as a matter of fact, make an experimental prediction about the superstition experiment just described. If the uncontingent reinforcers are presented at fairly frequent intervals, we will note the relatively rapid development of some arbitrary and perhaps bizarre behavior that will be fairly resistant to drift, that is, it will maintain a roughly similar topography over long periods of time. If the uncontingent reinforcements are delivered at less frequent intervals, we will note a susceptibility to change and drift in the accidentally reinforced behavior. In the extreme, if the uncontingent reinforcers are delivered at widely spaced intervals, then the drift becomes such a dominating characteristic of the behavior that we fail to notice a long-range strengthening effect of the reinforcement at all. Our conclusion, therefore, is that for reinforcement to be maximally effective it must follow the to-be-reinforced response without delay.

Reinforcement and deprivation. A second dynamic property of reinforcement is its relationship to deprivation. Some environmental events will be effective as reinforcers only if the organism has been deprived of some commodity. Food, for example, is effective in controlling the behavior of an

animal only if that animal has been made hungry through food deprivation. Similarly, water can be used as a reinforcer only if the animal has been deprived of water. Other kinds of reinforcers, even at the level of lower organisms, can be effective in the absence of deprivation. Electric shock, for example, can serve as a very powerful negative reinforcer without the organism having been deprived of any commodity such as food or water. It is no accident that negative reinforcement is the most popular form of behavior control employed by the average person. It is easy to dispense in its varied forms, and it does not depend for its effect on some prior operation not under the control of the punisher, such as deprivation of the punisher. Many of us have met individuals who through some quirk of behavioral development are themselves positively reinforced by their own dispensation of negative reinforcement.

Novelty as a reinforcer. There is now evidence to indicate that even at the level of the rat, a novel situation may serve to reinforce positively and to maintain exploratory behavior (Montgomery 1954). It is clear, however, that deprivation-independent reinforcers become more important as one ascends the phylogenetic scale. It has been demonstrated quite clearly that at the level of the monkey, behavior may be reinforced and maintained if the monkey has a brief opportunity to look out from an experimental chamber into a room that is occupied by other monkeys or by people (Butler 1953). Curiosity, then, is a motive in higher animals, and curiosity satisfaction is a potent reinforcer.

Generalized reinforcers. Reinforcers such as food and water and oxygen are of obvious importance in the control of lower animals. Of course they can also serve to control the behavior of higher animals. Ordinarily, however, the behavior of higher animals is under the control of nonhomeostatic reinforcers. A child, for example, can be powerfully reinforced by some particular play activity or by some manipulatable novel object, such as a brightly colored toy or a plastic ring. Adult humans can be powerfully reinforced by a wide range of reinforcers that we refer to as *generalized reinforcers*. These may be defined as specific events or objects that can be used to reinforce a wide range of different behaviors across many motivational systems, both homeostatic and non-homeostatic. In the life of human beings, the most obvious example of a generalized reinforcer is money. More subtle, but nonetheless just as powerful, are such reinforcers as praise, attention, and improvement in living standard and working con-

ditions. It is interesting to note that "improvement in working conditions" can serve as a reinforcer for the behavior of lower animals also. It has been demonstrated, for example, that a pigeon will peck at one key when the sole consequence of behavior on that key is to change the schedule of reinforcement to a more favorable one on a second key (Findley 1958). A more favorable schedule may be defined either by a higher rate of reinforcement or less work per reinforcement.

Physiological mechanisms. Finally, a recent finding offers considerable promise for the laboratory study of the physiological mechanisms of reinforcement. It has been demonstrated by Olds and Milner (1954) that such animals as rats and cats will work to produce weak electrical stimulation of certain brain loci. The technique holds great promise for the study of the neural substrates of reward. Olds (1962) has recently summarized most of the studies on reward by electrical stimulation of the brain.

V

DISCRIMINATION LEARNING

Discrimination learning, or the acquisition of ability to respond differentially to objects in the environment, is of continuing interest to psychologists for both empirical and theoretical reasons. Its study provides an opportunity for exploring the sensory capacities of the nonverbal organism, as well as the possibility of relating the fields of learning, perception, and attention, a possibility that has motivated much of the theoretical speculation available on this subject. Before attempting to evaluate the progress made in this direction, however, it is helpful to outline the most common procedures used in studying the learning of discriminations, most of which have employed laboratory animals.

Simultaneous discrimination procedure. In a simultaneous discrimination procedure, the animal is usually confronted with two stimulus objects on each trial. These objects normally are alike in all respects except for variation on some given attribute such as brightness, color, or shape. The animal indicates its choice between them by some reaction such as picking one up, approaching one, or the like. A "correct" choice is rewarded with something desirable, perhaps a pellet of food. An incorrect choice is nonrewarded or even punished.

Initially, of course, the animal shows only a chance level of accuracy because it has no prior knowledge of which object is related to reward and which to punishment. With continued training, the percentage of successful choices may increase to the point where it is clear the animal has mastered the problem. When the appropriate experimental controls have been used, such performance is clear evidence that the animal is sensitive to the stimulus attribute under investigation. The experimenter may then decrease the difference between the two objects. As he continues to do this, the animal's accuracy again approaches a chance level. From these data, it is possible to determine the animal's differential sensitivity to values on this stimulus attribute.

Successive discrimination procedure. In a successive discrimination procedure, only one of the two stimulus objects is presented on a given trial, but each occurs equally often in a sequence of such trials. In a T maze, for example, the stimulus object is displayed at the choice point, and the animal has the alternatives of turning into either the right or left alley. If turning left is the correct and rewarded response to one of the objects, then turning right is the correct and rewarded response in the presence of the second object. Thus, a different reaction must be related to each of the two stimulus objects in order to master the successive discrimination.

Alternatively, the animal's choice may be between reacting and not reacting. In classical conditioning procedures, for example, the animal is required to make the conditioned response in the presence of one object, the positive stimulus, and to inhibit this response in the presence of a different object, the negative stimulus. This technique has been valuable in determining absolute thresholds, that is, the minimum amount of an attribute that the animal can detect. Once the discrimination is established, the intensity or amount of the positive stimulus is gradually reduced until the animal no longer responds to it.

Generalization and discrimination. Theoretical interest in discrimination learning has tended to concentrate on two opposing tendencies that the animal shows during training. If it has been trained to respond in some definite manner to one stimulus, it will generalize or transfer this tendency to respond to a wide variety of other similar stimuli. This occurs spontaneously, without any specific training with these new stimuli. This tendency to generalize is of considerable interest to the theorist because it is one obvious basis for the transfer of training. But at the same time it poses a problem

for him. He must not only indicate the conditions under which this tendency to generalize is aroused, but he must also explain why this generalization occurs for certain new stimuli but not for others.

An opposing tendency, however, is also evident during discrimination training. Using the procedures described above, the animal can be taught to make differential responses to two very similar stimuli, that is, stimuli that would otherwise evoke quite similar responses in accordance with the generalization tendency. But during the course of discrimination training this generalization tendency is suppressed. The animal now acts as though the two stimuli were perceived as being distinctly different. Thus, a focal problem for a theory of discrimination learning is to explain the disappearance or suppression of the tendency to generalize as a result of the training procedures used.

Hull's theory. One of the more influential accounts of discrimination learning was developed by Clark Hull (1943). This formulation has two unique features. First, it does not attempt to explain the tendency to generalize; instead it assumes that it is an innate and universal characteristic of all organisms. Second, it accounts for the partial suppression of this tendency during discrimination learning by postulating a second and opposing form of generalization.

Hull's basic formulation is that every time an animal's response to a stimulus object is followed by a reward, there is an increase in the probability that the animal will respond in the same way to that stimulus object the next time it is presented. This is the excitatory tendency, the tendency to respond. This excitatory tendency, however, is not specific to the rewarded stimulus. It generalizes or spreads to other stimuli in direct proportion to the degree of similarity they have to the rewarded stimulus. This differential spread is conceived of as a generalization gradient. The amount of excitatory tendency is greatest for the rewarded stimulus, but this amount diminishes along a continuum of decreasing stimulus similarity. Basically, this conception is a description of what is empirically observed in transfer-of-training studies.

The suppression of this generalization tendency during discrimination training is accounted for by postulating an opposing tendency. It is assumed that each time the animal's response to a stimulus is not rewarded there is an increase in the strength of an inhibitory tendency, the tendency to withhold or suppress the response in the presence of that stimulus. This inhibitory tendency also generalizes. It forms a gradient that has a maximum value at the nonrewarded stimulus and that diminishes in

magnitude along a continuum of decreasing stimulus similarity.

In these terms, a conditioned discrimination can be conceived of in the following way. On some trials the animal is confronted by one stimulus and on the remainder of the trials by a second, similar stimulus. If it responds appropriately to the first stimulus, the positive one, it is rewarded. Thus, some amount of the excitatory tendency is associated with this stimulus and generalizes, although to a lesser degree, to the second stimulus. However, if the animal responds in the same way when this second or negative stimulus is presented, no reward is given. This results in a certain amount of inhibitory tendency becoming associated with the negative stimulus. This in turn generalizes, although to a lesser degree, to the positive stimulus. It is assumed that these successive interactions between excitatory and inhibitory processes continue during discrimination training until the following two conditions occur: (1) the excitatory tendency associated with the positive stimulus clearly outweighs the inhibitory tendency that has generalized to this stimulus, and (2) the converse is true for the negative stimulus. At this point the animal shows clear-cut discrimination behavior by responding appropriately on each trial to the positive stimulus and withholding that response to the negative one.

When stated more exactly, this formulation has a wide range of implications concerning the rates of learning to be expected in various discrimination tasks, the types of transfer or transposition behavior that should occur, and the like. A sufficient number of these implications have received empirical support to justify considerable faith in this approach. At the same time, these empirical studies have indicated a number of weaknesses in the basic concepts of the formulation. Perhaps the most important of these weaknesses is the absence of any means of defining the degree of similarity between two stimuli independently of the observed generalization behavior of the animal. This suggestion of circularity in the system has led in large part to a number of alternative formulations of discrimination learning.

The concept of similarity. In the psychological literature, stimulus similarity has been treated as a response-inferred construct. This means that the degree of similarity between two stimulus objects can be inferred only from the behavior of the animal with respect to them. If the stimuli are equivalent in the sense of producing comparable reactions, then, psychologically, they are highly similar for that animal. Phrased in this way, a theoretical account of the concept of similarity must state the

conditions under which the animal will treat two stimulus objects as though they were equivalent. This can be done either in terms of assumptions about the make-up of the organism or in terms of the physical properties of the stimulus objects.

Organismic attributes. One possible approach to this concept of similarity stems from the early work of Pavlov (1927). He claimed that similarity was largely a function of the neurological organization of the animal's cortex. Whether an animal perceives two stimuli as similar, as inferred from the generalization of behavior from one to the other, depends upon the spatial proximity of the sensory projections associated with these stimuli. If these are close together, considerable interaction or generalization can occur. With wider separations, the stimulus objects are perceived as independent or nonsimilar units. These neurological assumptions about the basis of similarity continue to have some influence in the physiological literature but have had little influence on psychological theorizing.

Stimulus attributes. Recent theoretical interest has centered on the possibility of defining similarity in terms of overlap or of common elements in the two stimulus objects. This approach was prominent in the writings of Thorndike ([1913] 1921, chapter 4) and Guthrie (1935) but has been given a much more precise formulation in statistical learning theory (Estes 1959). The basic notion in this approach is that each stimulus object, plus the stimulus context in which it appears, is to be conceived of as potentially a population, or large set, of stimulus elements rather than as a single, unanalyzable unit. On a given trial the animal experiences only a randomly selected sample, or subset, of this potential population of elements that constitutes the object. This trial-to-trial variability in the sample of elements experienced is due to a number of factors; it stems in part from the impossibility of exactly reproducing the physical stimulus situation, in part from moment-to-moment variation in the state of an organism, in part from changes in the postural orientation of the animal with respect to the stimulus object, and so on. In order for the animal to experience all the elements in the population, it must be exposed repeatedly to the same stimulus object.

With two stimulus objects, of course, there are two populations of stimulus elements. Some of these elements may be common to the two populations, the rest being specific to one or the other. The proportion of common elements to the total number of elements in the combined populations is one possible measure of the degree of similarity between the two stimulus objects. The greater the

proportion of overlapping elements, the greater is the degree of similarity.

The unique feature of this conception of similarity is that it does away with the need to assume that the animal has an innate tendency to generalize its learned behaviors. If an animal does transfer such a response from a training stimulus to a new one, it is because the populations of elements constituting the two objects have elements in common. These common elements were associated with the learned response during training with the first stimulus object. Consequently, there is a definite probability that they will evoke that same response when they again occur in the context of the new stimulus object. The probability that this generalization will occur increases as the proportion of overlapping elements in the two populations increases; the larger this degree of overlap, the more likely it becomes that any one sampling from the new stimulus object will contain a large number of them.

The assumptions underlying this conception of similarity have been stated mathematically in several recent formulations of statistical learning theory, making possible much more precise statements as to when generalization will occur and the amount of such transfer to be expected. As these predictions have considerable empirical support, it would appear that a real advance has been made in understanding the basis for psychological similarity.

Paradoxically, however, the success of this approach in predicting generalization has led to an impasse in attempting to apply the same assumptions to discrimination learning. If taken in its most literal form, this conception of similarity as being due to overlapping stimulus elements implies that an animal can never achieve a perfect discrimination between two similar stimulus objects, since their common elements would always be associated with each of the different responses, an implication that is clearly at variance with empirical observation.

Consequently, if this conception of similarity in terms of common elements is to apply to discrimination learning, as well as to generalization situations, additional assumptions must be made concerning these stimulus populations. One possibility is that their composition of elements is modified during discrimination training. In some sense the number of common elements is reduced, or at least their control over choice behavior is minimized [see GUTHRIE; THORNDIKE].

Selective attention. In a different context, the idea that the effective stimuli for behavior are modified or transformed during the course of

learning has been discussed under the heading of selective attention. Two conceptualizations of this transformation process have been suggested. One of these involves the enrichment of, or additions to, the effective stimulus; the other emphasizes a reduction in the content of the stimulus.

Enrichment of the effective stimulus. The enrichment idea was clearly formulated by William James (1890, pp. 508 ff. in volume 1 of 1950 edition). He denied that the immediate sensory input from the stimulus object is the direct elicitor of choice behavior. Instead, he suggested that the effective stimulus is the complex of ideas, emotions, and other reactions that are associated with this sensory input. The main implication of this formulation is that the complexes associated with two stimulus objects may have proportionately less overlap and fewer common elements than do the immediate sensory experiences that give rise to them. Consequently, the tendency to generalize is reduced as these differentiating complexes develop during the course of learning. In more recent discussions of discrimination learning, this notion has been formulated somewhat more explicitly in terms of the concept of the "acquired distinctiveness of cues" (Miller & Dollard 1941).

Elimination of irrelevant cues. A more popular approach to the problem, however, is to view the stimulus transformation process as one in which the initial sensory inputs are gradually stripped of all irrelevant or nondifferentiating aspects. Only the differentiating, nonoverlapping aspects remain as the effective stimulus for the choice behavior. The simplest of these formulations postulates the learning of receptor-orienting behaviors. If, for instance, an animal looks at the top halves of two stimulus objects, the sensory input from them is likely to be quite different than if the animal looks at the bottom halves. Consequently, the animal may learn that certain receptor orientations lead to a more accurate discrimination than would be otherwise possible insofar as these sensory inputs contain a minimum number of common aspects and a maximum number of differentiating aspects. Learned orienting behaviors of this sort undoubtedly are involved in many types of discrimination, but the concept would seem to be of quite limited usefulness in situations where there is minimal need or opportunity for visual search procedures.

Stimulus coding. A number of alternative mechanisms have been proposed to account for the selective aspects of attention. These are variously referred to as "filter theory" (Broadbent 1961), "analyzer mechanisms" (Sutherland 1959), or "stimulus coding behaviors" (Lawrence 1963).

While these differ in many details, the general approach can be illustrated in terms of stimulus coding behaviors.

The stimulus coding formulation recognizes that the sensory input at any moment depends as much on the behavior of the organism as it does on the characteristics of the external stimulus object. For instance, the tactual sensations from a piece of sandpaper are quite different depending upon whether the individual merely places a finger tip on it or draws a finger rapidly across the surface. Thus, the effective stimulus to which the individual reacts is a joint function of his own behavior and the characteristics of the stimulus object.

In order to allow for both of these factors in determining the effective stimulus, the stimulus coding formulation assumes that the total sensory input from the discrimination situation is functionally divided into two parts. The first part corresponds to the stable, recurring aspects of the situation and the second part to the changing, variable aspects. In a successive discrimination, the stable part of the input may correspond to the characteristics of the room, the apparatus, and the like; the variable aspects may correspond to the characteristics of the stimulus objects to be discriminated.

It is assumed that the stable aspects of the situation become associated with, and control, an implicit, inferred coding response. When this coding response is elicited, it reacts on, or interacts with, the sensory input from the stimulus object. As a result of this interaction, a new input is generated which is called the "coded stimulus." When, as in discrimination learning, there are two different stimulus objects but only one coding response, two different coded stimuli are produced. These control the choice behavior.

In this schema, the characteristics of the coded stimuli change whenever there is a change in the coding response even though the stimulus objects remain constant. The coded stimuli are resultants from an interaction between a coding response and the immediate sensory inputs. A change in either the coding response or the immediate sensory inputs modifies the coded stimuli. The range of values the coded stimuli can assume, however, is limited by the actual properties of the sensory inputs. These latter are members of the interaction, and therefore the resultants cannot be independent of them. The implication is that these coded stimuli correspond to parts of, relationships within, or other limited aspects of the sensory input. But even with this restriction, the coded stimuli can vary greatly with changes in the coding response.

To complete the formulation, it is assumed that

the coding response varies in a trial-and-error fashion during the initial stages of discrimination learning. Gradually, however, it shifts in that direction which tends to minimize the confusion and overlap between the coded stimuli. This is, of course, the direction that maximizes the accuracy of the discrimination. Thus, a dual learning process is always involved in a discrimination procedure: The animal must discover a coding response that produces highly distinctive coded stimuli, and at the same time learn which overt choice reactions are appropriate to these coded stimuli.

Formulations of this type offer a mechanism that permits the effective stimulus for behavior to be continuously modified throughout the course of learning. They permit the animal to react initially to the total stimulus input including the common, or overlapping, aspects. Thus, there can be the broad generalization characteristic of such situations. But with experience, the effective stimulus shifts in the direction that corresponds to the differentiating, nonoverlapping aspects of the stimulus objects. This ensures a high level of accuracy for the discrimination and offers a solution to the dilemma encountered in statistical learning theory. On the other hand, it is obvious that these formulations once again make stimulus similarity a direct function of the animal's own behavior.

Additional aspects. It should be emphasized, however, that even more precise and powerful theories of this type would not do justice to the wide range of empirical effects found during discrimination learning. The experimental literature contains many suggestions of changes in response selectivity, of heightened motivational effects, and of conflict resolution that largely fall outside the bounds of any of the theoretical approaches so far mentioned.

A clear example of changes in response selectivity is provided by the studies on learning set (Harlow 1959). These demonstrate that an animal can solve simultaneous discriminations with incredible rapidity after repeated experience with this class of problems. A sophisticated monkey requires only one or two information trials to reach a high level of mastery, whereas initially it required a prolonged training period to solve an equivalent problem. An analysis of this type of learning suggests that the increase in efficiency is in part due to the elimination of the response biases so prominent in the naive animal, for example, such biases as position preferences, alternation tendencies, or tendencies toward perseveration in a given response.

Motivational changes are apparent in studies on

contrast effects. Pavlov first demonstrated these in his studies on positive and negative induction. He found that once a successive discrimination was established by conditioning procedures, a series of presentations of the positive or rewarded stimulus object tended to strengthen and maintain the inhibitory tendencies evoked by the negative stimulus object. This was true even though the negative stimulus object was now followed by reward. Conversely, a series of presentations of the negative or nonrewarded stimulus object tended to strengthen and maintain the excitatory tendency evoked by the positive stimulus object, even though this was no longer rewarded. Descriptively, it is as though the animal has built up a set of contrasts as the result of discrimination training: experience with the positive stimulus object increases the undesirability of the nonrewarded behavior, and experience with the negative stimulus object enhances the desirability of the rewarded behavior. Comparable phenomena have been demonstrated with other types of discrimination training.

Related to these contrast effects are any number of phenomena that can be grouped in terms of conflict resolution. Perhaps the most dramatic of these is the change in behavior that occurs in experimental neurosis (Liddell 1956). After a successive discrimination is well established, the two stimulus objects are made more and more similar until the animal is unable to discriminate between them. Occasionally, under these conditions, the animal begins to show agitated and highly emotional behavior. This emotionality persists for long periods of time both in the experimental situation and in other contexts. Equally impressive are the abortive and stereotypic behaviors exhibited by animals who have been frustrated by being forced to respond in an unsolvable discrimination situation (Maier 1949).

This brief and highly selected survey of the many behavioral changes that occur during discrimination learning is sufficient to indicate the limitations of present theories on this subject. These formulations have been primarily concerned with developing appropriate concepts to deal with generalization phenomena, stimulus similarity, and selective attention. They obviously have not dealt adequately, as yet, with the phenomena of response selectivity, motivational changes, and conflict resolution.

VI

AVOIDANCE LEARNING

In avoidance learning the organism comes to behave in an anticipatory or foresightful manner in order that unpleasant events no longer will occur. It learns to respond to certain cues or danger sig-

nals before painful or frightening stimuli can occur, and it performs acts that usually prevent the painful events from occurring. In the following account empirical generalizations are emphasized to demonstrate the wide variety of variables operating in avoidance learning. In some cases these generalizations are not very well established, and so they represent only the current state of affairs and are always subject to change as more experiments are reported. Avoidance learning represents an empirical focus today, and hundreds of experiments each year are completed in this area of science. Empirical findings have clearly outstripped adequate theoretical accounts of the avoidance learning process.

Avoidance training experiments of a scientific sort have, for obvious humanitarian and ethical reasons, been confined mainly to animal subjects. There have been few experiments in which human subjects were studied, and those experiments have yielded results quite similar to those obtained in animal experiments. There is every reason to believe that the variables in control of animal avoidance learning are not very different across mammalian species.

Two different types of training

Active avoidance. Imagine, if you will, a white rat placed by an experimenter (*E*) into a small training box. The floor of the box is an electrifiable grid of metal rods. At a height of 10 inches above the floor and hinged as a shelf to the side of the box is a small platform. The lid of the box is a transparent plastic plate, and above it is suspended a 60-watt lamp. *E* allows his subject *S*, the rat, to explore the box for a few minutes. Then training begins. *E* switches on the light above the rat box for a 30-second period. *S* continues his sniffing and exploring during the switching on and off of the light. *E* repeats the procedure 5 times, noting that *S* does not jump onto the platform. Then *E* switches on the light, waits for 5 seconds, and turns on the power supply which electrifies the metal grid floor of the box and shocks *S*. *S* squeals, rushes about, leaps into the air, and then, 12 seconds after the shock is turned on, jumps onto the platform where there is no shock. As *S* lands, *E* turns off the light. One minute later, the hinged shelf is momentarily lowered, dropping *S* onto the grid again. Then 2 minutes later, a second training trial is begun. The light goes on, and 5 seconds later the shock goes on. The rat leaps onto the platform 4 seconds after the shock goes on.

The rat's performance has improved in two trials of training. We say he is learning to *escape* from

shock. After several escape training trials have gone by, *S* eventually will respond directly to the onset of the light, and he will jump onto the platform without the stimulus of shock. This jump is called an *avoidance* response. By this response, *S* avoids the shock, and since the light is turned off when he jumps onto the platform, he also *escapes* the light.

S has learned to respond in an anticipatory fashion in such a way that if he jumps quickly at the onset of the light he will never again receive the shock. This type of process is called *active* avoidance learning. *S* is taught *what to do* to minimize pain and distress. Note that he is punished for doing everything else but jumping onto the platform whenever the light goes on. He is, therefore, not being taught anything specific that he should *not do*. In the active avoidance training procedure, the light is usually called the *discriminative stimulus* (S^d), *cue*, or *signal*; the shock is called the *unconditioned stimulus* (US). Because the escape responses are instrumental in terminating the shock and the light and because the avoidance responses are instrumental in preventing the shock and terminating the light, they are often called *instrumental* responses. They change the environment in such a way as to make it more acceptable to the subject. They *operate* on the environment and so are often called *operants*.

Passive avoidance. A somewhat different yet very important avoidance training procedure produces *passive* avoidance learning. Passive avoidance training corresponds to our everyday conception of *punishment*. In this procedure *S* is taught specifically *what not to do*, but he is not taught *what to do*.

Imagine now that another white rat is placed by *E* on the platform of the small training box. This *S* is hungry, and *E* has placed a food pellet for him on the grid floor. After some hesitation, *S* scrambles down from the platform and eats the food pellet. *E* then picks *S* up and places him on the platform again. This time *S* jumps down more quickly than he did on the first trial, and he again eats a food pellet. After many trials, *S* shows stable food-getting behavior; he jumps down quickly and uniformly on each training trial. Now *E* can get rid of this instrumental response (jumping off the platform) by means of *passive* avoidance training. *E* electrifies the grid whenever *S* jumps down to get a pellet. Eventually, *S* will stay on the platform rather than jump down. *S* has learned to avoid shock by avoiding specific action. What *S* does when on the platform is *not* being specified by the training procedure, and so *anything* he does, as

long as it does not lead him to the grid floor, goes unpunished.

Active and passive avoidance learning can take place under a wide variety of training procedures, and the characteristics of learning depend heavily on the type of procedure *E* uses.

Variants of the two types of training

Active avoidance. Six important variants of the active avoidance procedure warrant discussion.

The method of gradual emergence. By use of the general training conditions described under active avoidance, it can be shown that *S* will learn avoidance responses either very suddenly or very gradually by varying the training techniques. For example, when small movements or reflexive responses are selected by *E* to be the active avoidance responses, learning is slow and tortuous. Forepaw flexion responses in the dog often require several hundred training trials in order to establish them as reliable avoidance responses. The same is true of a tiny toe movement in human *Ss*. In contrast, massive movements that change the *S*'s environment are quick to emerge as reliable avoidance responses. Requiring a rat to jump onto a platform, as described above, requiring a dog to jump from one compartment of a box to another, or requiring a human *S* to push a knob a distance of 2 feet—all three are examples of efficient situations for producing sudden and reliable avoidance learning. A way of interpreting these findings is that medium-probability operants make the best avoidance responses, while high-probability, short-latency respondents (reflexes) make the poorest avoidance responses.

A characteristic of some avoidance responses is their persistence. In general, those training conditions leading to efficient learning also lead to a high degree of resistance to extinction. Such responses as the jumping onto a platform described above can persist over hundreds of trials without a shock being administered. This is not likely to be true of responses like forelimb flexion or toe flexion. The persistence of avoidance responses, as an empirical phenomenon, has extensive implications for studies of human neuroses. Long-lasting phobias, obsessive and compulsive behavior, and neurotic defenses of many types can be fruitfully analyzed in terms of the special experimental conditions that established such behavioral rigidity. Sometimes therapeutic treatments are deduced from such analyses. [See **OBSESSIVE-COMPULSIVE DISORDERS; PHOBIAS.**]

Other variables influencing the ease of active avoidance learning and, inversely, the ease of extinction are the *S*^d-*US* time interval, the intensity

of the *US*, the similarity of the *S*^d to the *US*, the immediacy of termination of the *US* and the *S*^d after the performance by *S* of the avoidance response, and the occurrence of events arousing responses that are incompatible with the required avoidance response. Usually, there is an optimum *S*^d-*US* interval for each type of avoidance response. If an avoidance response is a long-latency, complex operant, a long *S*^d-*US* interval of perhaps 5 to 10 seconds will be optimal. For short-latency, reflexive types of avoidance responses, short *S*^d-*US* intervals of around 1 to 2 seconds will be optimal. Usually, for a given type of avoidance response, lengthening the *S*^d-*US* interval beyond the optimal interval will facilitate extinction of the response when shock is no longer administered.

Shock intensity complexly influences avoidance learning. There is an optimum intensity for each type of response, and intensities lower or higher than the optimum will retard learning and facilitate extinction. The optimum intensity decreases as the complexity of the avoidance response increases. This is known as the Yerkes-Dodson law. When the *S*^d is frightening, learning is more rapid than when it is neutral. Thus, a mild shock used as an *S*^d will facilitate learning, as will a frightening buzzer. A nonfrightening light may be less efficient in controlling stable avoidances. Delaying either the termination of shock following an escape response, or the termination of the *S*^d following an avoidance response, or both, will retard avoidance learning, and even short delays of about 5 seconds may make it impossible for *S* to learn. Finally, some avoidance responses are incompatible with the innate fear responses of *S* and can interfere with correct responses as fear increases. For example, when *S* is a rat, we have to try to eliminate innate "freezing" reactions that often occur when the *S*^d becomes fear-arousing as a result of its association in time with the painful *US*. Often a rat will "freeze" when the *S*^d goes on and thus fail to avoid during the *S*^d-*US* time interval. He may escape easily as soon as the shock goes on if the shock is of an appropriate intensity for vigorous behavior arousal. One way of eliminating freezing is to decrease *US* intensity. Another way is to increase the *S*^d-*US* interval. Quite often, however, *S* fails to avoid in many experimental situations, and these failures have not yet been analyzed sufficiently by psychologists. Rather, they tend to be ignored as accidents or are attributed to unspecified individual differences. They represent an area of ignorance.

Most successful avoidance learning in the method of gradual emergence is characterized by a high level of fear and emotionality early in learning.

when shocks are still being administered, followed by declining emotionality when the avoidance responses become reliable. Along with these correlated events, the topography of the avoidance responses themselves becomes stereotyped. When this stereotypy occurs, extinction is not easy to produce by constant elicitation of the responses.

The method of prior response shaping. In the method of prior response shaping, the *S* is first trained to escape the *US* without a signaling *S^d*. After *S* is an expert escaper, the warning signal or *S^d* is paired with the *US*. Using this method, the avoidance responses are very much like the escape responses. In contrast, the method of gradual emergence often produces avoidance responses different in appearance from the escape responses from which they were derived.

*Escape with short *S^d*-*US* interval.* When the *S^d*-*US* interval is too short to allow avoidances, except on test trials when the *S^d* is presented without the *US*, very poor avoiding is produced along with reliable and short-latency escaping. The *S* is usually very fearful and emotionally disturbed.

The method of prior fear conditioning. In the method of prior fear conditioning, the *S^d* and *US* are paired closely in time on each trial, but there is at first no escape or avoidance response available to *S*. He merely learns to fear the *S^d*. After many trials, *S* is then allowed to terminate the *S^d* by means of a response in his repertory. If such a response is emitted in the presence of the *S^d*, the response is quickly adopted by *S* as a reliable avoidance response. On the other hand, *S* often does not make the required response, and so he never learns. Failures of this type are frequently produced by this method. Extinction of avoidance responses appears to occur more readily by this method than by the method of gradual emergence. This method is sometimes called the "acquired drive" experiment.

The Pavlovian method. In the Pavlovian procedure, *E* presents *S* with an *S^d*-*US* sequence repeatedly, but *S* cannot do anything either to prevent or to terminate the painful *US*. Instead, the *US* is omitted on test trials, and sometimes the *S* will demonstrate a consistent type of anticipatory or preparatory response pattern. Russian physiologists call this method "motor conditioning." When many test trials are run, we note that the *US* does not occur no matter what anticipatory responses may be evoked by the *S^d*. Thus, such trials are like avoidance-response trials in other methods. Despite this, very unstable learning occurs. Often the response consists of constantly varying struggling and diffuse emotional expressions.

The Sidman method. In the Sidman procedure,

no *S^d* is used (although one can be used). Instead, the *US* is regularly presented if *S* does not perform a particular response desired by *E*. If *S* does perform the required response, the *US* is delayed for a fixed time interval. The avoidance response thus "buys" shock-free time for *S*. Note that the *US*-*US* interval can be varied independently of the response-*US* interval. If an *S^d* is used, it can come anywhere in the *US*-*US* interval or in the response-*US* interval. This method can produce very stable avoidance responding and high resistance to extinction. There are, however, many individual failures of rats to learn. These failures can be reduced if the avoidance response is capable of terminating the *US*. This method is especially interesting because *Ss* often develop stable response rates, with the avoidance responses appearing at regular intervals. The responses appear to be under the control of some type of "internal time mechanism" that serves as an *S^d* substitute. As long as this mechanism elicits responses at interresponse time intervals less than the response-shock interval, *S* never receives a shock. The method is often viewed as revelatory of the build-up in time of "conditioned anxiety"; whenever the anxiety becomes intolerable during the response-shock interval, *S* makes another response. The similarity of this phenomenon to human compulsive neuroses is often pointed out.

Passive avoidance. Two major variants of the passive avoidance procedure will be discussed.

Punishment methods. There are two general types of punishment techniques. One technique used in the punishment method is illustrated by the general example given above to describe passive avoidance training in the rat. The rat is presented with a painful *US* contingent upon each jump from the platform to the grid floor of the training box.

The second technique, called the secondary aversive stimulus technique, establishes a previously neutral stimulus as an aversive CS (conditioned stimulus) by pairing it in time with several presentations of a painful or frightening *US*. When the CS evokes an acquired fear or anxiety reaction, called the "conditioned emotional response" (CER), the CS is then used to punish a specific type of behavior. The example we used above to illustrate passive avoidance learning would have been a secondary aversive stimulus technique if the rat, instead of being shocked for jumping down to the food, had been presented with a CS previously paired with shock.

Punishment procedures may be applied in an attempt to eliminate at least five different types of behavior: (1) an instrumental response previously

established by rewards, illustrated by punishing the rat for jumping off the platform to get food; (2) an *instrumental* response previously established by punishment, illustrated by punishing a shock avoidance response with another frightening stimulus; (3) a *consummatory* response, such as eating, drinking, or copulating; (4) a complex, *instinctive* response pattern, such as nest building in birds; and (5) a simple *reflexive* reaction, such as an eye-blink. The results obtained by punishment procedures differ for each of these five categories.

First, when an instrumental response that has been previously established by rewards is punished, the outcome depends heavily on: (1) *duration* of the punishing stimulus—short-duration punishments that are presented after the response has occurred usually produce temporary suppression of the response and are followed by recovery of the response (sometimes to supernormal levels), while long-duration stimuli often suppress the punished behavior for long time intervals; (2) *intensity* of the punishing stimulus—low-intensity punishing stimuli will suppress behavior temporarily, but the behavior recovers, often to a level more vigorous than that prior to the use of punishment, but high-intensity punishing stimuli will often suppress behavior for long periods of time; (3) *delay of punishment*—the sooner the punishing stimulus is applied after an unwanted response has occurred the more effective will the punishment be, giving us what is known as the “temporal gradient of delay of punishment”; (4) *repeated exposure*—Ss often show some adaptation to repeated punishments, and, therefore, new punishments are often more effective than familiar ones, provided of course that their duration and intensities are equal; (5) *reward-punishment habituation*—if a response is simultaneously rewarded and punished and if the punishment is of low intensity and duration, sometimes the punishment will not only be ineffective in suppressing the response but will also be able to serve as a reward in its own right (this is similar to masochism in neurotic disturbances); (6) *existence of a rewarded alternative*—if alternative response A is punished and alternative B is quickly rewarded, the punishment will be very effective in suppressing A, but when there is no rewarded alternative to A, the response will recover more quickly from the suppressing effects of punishment; (7) *temporal discriminative alternatives*—the housebroken dog learns to urinate under condition A (outdoors) and never to urinate under condition B (indoors), provided that frequent punishment for B is followed quickly in time by no punishment for A (this is often re-

ferred to as “impulse control” training); (8) *temporal order of reward and punishment*—when a reward is followed regularly by punishment, the behavior leading to the reward is often suppressed, but if exactly the same behavior is evoked by punishment and then rewarded, the behavior can be strengthened, and S may come to tolerate the punishment or even to seek it out; (9) *species-specific characteristics*—a toy snake can be used to punish behavior in monkeys, but it does not bother a rat, for example; (10) the *resistance to extinction* of the response being punished—responses which would normally be extinguished quickly in the absence of reward will be suppressed more readily by punishment than will responses normally having a high resistance to regular extinction procedures.

Second, when an instrumental response that has been previously established as an active avoidance response is punished, the outcome is hard to predict. Sometimes the response intended by E to be suppressed by the punishment is actually energized. Probably this facilitation is produced most reliably when the punishing stimulus is very similar to or the same as that which was used as the US in the earlier avoidance training procedure. A good deal of ignorance exists in this field of study.

Third, when a consummatory response is punished, the suppression is very often long-lasting and emotionally disturbing. Punishment seems to be more effective when applied to this type of behavior than it is when used to suppress instrumental responses, for reasons that are at present quite mystifying.

Fourth, when punishment is used to suppress complex, species-specific, instinctive behavior patterns, the results are often confusing. Sometimes displacement occurs; that is, S shows behavior characteristics of another behavior pattern. Frightening an animal for courting behavior may induce nest-building behavior or other inappropriate acts.

Finally, little is known of the effects of punishment for specific reflexive behavior. This contingency happens frequently in everyday affairs, as when an involuntary act annoys others, but the phenomenon has not been studied systematically in the laboratory.

The CER method. The CER procedure differs from the punishment procedure in a subtle but evidently important way. No specific passive avoidance response is established. Thus, this method is similar to the punishment method. But, in contrast to the punishment method, the CER method does not apply a punishment to a specific response. Instead, a frightening, secondary aversive stimulus is added to the general surroundings of S for lim-

ited periods of time. Often the usual behavior in that environment is depressed in rate, or amplitude, or quickness. A typical example is as follows: a rat is trained to press a lever when he is hungry in order to obtain food pellets. After this lever pressing occurs at a reliable rate, the CER procedure is introduced. A previously neutral stimulus is now associated with shock in a special shock box (repeated CS-US pairings, with no escape or avoidance possible) and evokes a CER. When the CER stimulus is presented in the lever box, the lever-pressing rate often decreases. The CER stimulus is not presented contingent upon S's lever-pressing response. Rather, it occurs without regard to the behavior being rewarded by food. Despite this, the instrumental behavior is often suppressed. Indeed, the CER technique may often produce suppression as effectively as does the punishment method.

One major value of the CER procedure has been in the assessment of psychologically active drugs. Often, tranquilizers have been shown to minimize the response suppression attendant on the CER stimulus, and the special characteristics of behavior during the suppression period in drugged Ss can be of value in analyzing the action of the drug. The method has also been used to assess the level of fear controlled by a CS, assuming that the more the ongoing, appetitive, and instrumental behavior is suppressed, the more fear arousing is the CS. This dependent variable can then be related to events taking place during fear conditioning or to those occurring during avoidance training in which the same CS is used. For example, the S^d in avoidance training in situation A may not suppress appetitive behavior in situation B—thus leading to the conclusion that the S^d no longer arouses much fear. This finding has been correlated with observations of declining fear during stereotyped avoidance responding and with the finding that conditioned heart-rate elevation decreases during late phases of successful avoidance responding as the behavior becomes stereotyped. Thus, active and passive avoidance procedures can be combined to yield significant interrelationships between emotional reactions and instrumental responding.

Two of the most pressing questions concerning avoidance learning are theoretical ones. What mechanism produces the first avoidance response? What mechanism reinforces avoidance responses? Here, we are still in the dark. One explanatory scheme is cognitive. It argues that S comes to anticipate shock by virtue of S^d -US pairings and that S comes to know how to terminate shock by virtue

of escape responses. Then, by an insightful inference, S terminates the S^d by performing an avoidance response. Another explanatory scheme depends heavily on the James-Lange theory of emotion. It argues that the S^d -US pairings lead to conditioned fear (CER) in the presence of the S^d . When the CER is intense enough to be as arousing as the shock itself, then S does in the presence of the S^d what he has learned to do in the presence of the shock. He performs the escape response during the S^d -US interval, and so he comes to avoid. Avoidance responses remove the S^d , thus reducing the anxiety level, and so avoidances are reinforced by anxiety reduction. Finally, another explanatory scheme depends heavily on proprioceptive feedback arising from skeletal movements. It argues that S learns to avoid movements associated with shock, thus leaving S to perform only movements not associated with shock. Certain proprioceptive stimulus patterns acquire aversive properties during the escape training phase or, as in the Sidman method, during the phase of learning wherein the US is frequently presented. Avoidance of aversive proprioceptive stimulus patterns gradually "shapes up" the avoidance behavior. At the moment there seems to be no decisive evidence that would allow us to choose among the major explanatory alternatives. However, many current experiments are being aimed at the theoretical systems to probe their strengths and weaknesses in predicting important variables and phenomena.

VII

NEUROPHYSIOLOGICAL ASPECTS

How the brain changes as a result of an organism's experiences, how it maintains its altered state through time, and how it influences future behavior in a modified but systematic manner are some of the most intriguing mysteries facing modern biology. Direct experimental study of this problem started shortly after the turn of the century, a time when substantial neuroanatomical knowledge had already accumulated, although the electrical techniques that evolved into those of modern day neurophysiology were then in their simplest, primitive stages. By the 1920s, two pioneering behavioral scientists, Lashley (1929) in

the United States and Pavlov (1927) in Russia, were well along with their classical studies of learned behavior in animals and were attempting to relate their findings to the function of the brain.

Lashley, studying instrumental behavior in rats with experimentally created brain lesions, and Pavlov, theorizing about brain function from his studies of conditioned behavior in dogs, both focused their attention on the uppermost layer of the brain—the neocortex. The cortex, as it is more commonly called, gained early attention because of its greater size in man and the other higher animals. This anatomical fact suggested that the cortex might be particularly concerned with such complex neural processes as learning. It was not until the 1950s that investigations concerned with the physiology of the process of learning started to disengage themselves from the belief that the neocortex is exclusively responsible for the fixation of experience that permits new behavior patterns to be acquired.

From the standpoint of the nervous system, experience is some temporospatial pattern of transitory electrical activity in the nerve cells (neurons) of the brain. The basic neurophysiological question, then, is how can this evanescent neural activity modify the circuits of the brain so that they remain uniquely altered after the initiating physiological event has vanished. Any final understanding of this process requires answers to a number of interrelated and interlocking questions. First of all, how are the stimulus events that are to be learned electrophysiologically coded for introduction into the nervous system and transmission throughout the complex pathways of the brain? In what parts of the brain are the relevant coded messages integrated and stored for future use? How do electrical neural events, arising transitorily during initial learning, manage to induce a patterned and relatively permanent change in the brain, a change that is presumed to be chemical or structural? Finally, what is the physical nature of this semi-permanent brain cell change, which can persist in neural tissue for years despite the active metabolic turnover in neurons, and how does this cellular change selectively modify the brain's subsequent functioning so that the organism's behavior can be an adaptive synthesis of past experience and current environmental demands? These are questions that have dominated research in the neurophysiology of learning.

Electrophysiological aspects

The nerve impulse. Any speculation about the physical basis of learning has of course been

heavily influenced by the existing state of neurophysiological knowledge. The conspicuous electrical event that was first observed in the early studies of peripheral nerves was the nerve impulse, action potential, or spike, as it is variously called. This bioelectric activity is crucial in neural functioning and can be recorded from the stringlike extensions (fibers or axons) of all nerve cells. It is the nerve impulse, propagated along nerve fibers as the result of rapidly shifting chemical changes, that allows one neuron to influence the activity of other neurons with which it is in contact. At these points of contact (synapses), it is now known that the traveling nerve impulse induces the secretion of minute amounts of biochemical compounds (neurotransmitters) that, in turn, can influence the electrophysiological state of the next neuron in line. In this way, a nerve impulse can be initiated in the adjoining nerve cell.

It was early recognized that the basic nerve impulse was an all-or-none process. If the activation of a nerve cell reaches a given threshold, a spike of a predetermined size will be propagated at a given speed along the cell's axon. Further, once such a spike has developed and subsided (in several milliseconds at most), either in the initially stimulated neuron or in adjoining neurons via synaptic connections, there ensues a sequence of physiological changes (after potentials) that systematically influences the "firing" threshold of the cells for a brief time period. Over the span of about a tenth of a second, it is first more difficult and then easier to initiate a second spike. These were the primary facts of high-speed neural function that were available to behavioral scientists of the 1930s and early 1940s as they contemplated the overwhelming plasticity and long-term memory of the complex, multisynaptic brain.

Reverberating circuits and synaptic change. The first attempts to define the neurophysiological mechanisms that might provide the basis of learning were developed from these simple basics of brain function. Many more facts about the functioning of the central nervous system are now available, but the broad outlines of the generally accepted neurophysiological mechanism of learning have not changed in principle. It is still thought that nerve impulses, bombarding some combination of synapses in a pattern that is somehow appropriate to the task to be learned, bring about a change in the functional characteristics of the synapses and, thereafter, that particular pattern of nerve impulses will induce the response sequence that occurred during the original learning. Reverberating neuron circuits are thought capable of supplying the time necessary for the electrical activity to lead to

some form of permanent synaptic change that would account for the long-term behavioral changes that can follow a learning experience. Possibly the best-known statement of this point of view was that of the Canadian psychologist Donald O. Hebb, who suggested that the permanent neural changes might be based on the structural growth of appropriate axon endings at the synapse (Hebb 1949). His specific suggestion has yet to be proved or, for that matter, disproved.

Brain waves and electroencephalography. With improved electronic techniques that permit the direct study of brain activity, a variety of characteristics of brain function have been discovered. Neurophysiologists, for example, are looking with increased interest at the variety of slowly shifting electrical potentials that can be recorded throughout the central nervous system. Whereas the small spike of a primary nerve impulse, for example, can subside in less than a millisecond, these larger potentials can oscillate as slowly as several times a second. There are also even slower shifts of D.C. voltage, lasting seconds or even minutes. Certain of these slow potentials oscillate spontaneously even in the resting or sleeping brain. These are the brain waves seen in the well-known electroencephalogram (EEG). Although independently discovered in lower animals by R. Caton in England and A. Beck in Poland in 1875 and 1890, respectively, the EEG did not receive widespread attention until 1935, when the German psychiatrist Hans Berger reported that the same slow electrical rhythms were also evident in the human brain. The EEG remained largely a clinical tool, little used in behavioral research, until some of its neural and behavioral correlates started to be better understood because of the classic study made by the Italian neurophysiologist Giuseppe Moruzzi and his American collaborator, H. W. Magoun, in 1949. These investigators, together with many that followed them, showed that the EEG could serve as an indicator of arousal (or the lack of it) in the cortex as a whole or in restricted centers within the brain (Magoun 1958). As we shall see, behavioral scientists have subsequently started to use the EEG to evaluate the level of activity in various brain centers during different stages of learning.

Horizontal versus vertical organization

Aside from the more specific question of which particular structures within the brain may be necessary for learning, there is the prior but related question concerning the general flow of brain activities during complex behavior in general and learning in particular. General attitudes concerning this matter have shifted considerably during the

half century or so since the beginning of direct laboratory study of brain mechanisms and learning.

Horizontal organization—association areas. The earliest point of view, and still the most common oversimplification of the facts, placed almost exclusive faith in the importance of the multilayered neocortex, which is conveniently located at the top of the central nervous system. As we have seen, the pattern of the phylogenetic development of the brain conspicuously pointed to the increased size of the cortex as the most likely source of control for such higher mental processes as learning. In its most traditional form, this corticocentric frame of reference also emphasized the horizontal organization of the neural substrate of learning, which is presumed to take place in the transcortical pathways that connect the sensory and motor areas of the neocortex. The so-called association areas, located between the sensory-input and motor-output areas, were assumed to supply pools of synapses where changes in transmission characteristics could afford new patterns of transcortical connections that would provide for the changing patterns of learned behavior. The highly influential Pavlovian theory of learning was like this in general form, the transcortical effects being visualized as irradiating neural influences between sensory and motor areas in the cortex.

Vertical organization. Along with the recent growth of interest in the role of subcortical structures in all varieties of behavior, there has developed a newer point of view, which emphasizes the vertical organization of the brain and the recurrent interactions between neural centers at all levels of the central nervous system, including the cortex. Possibly the most convincing evidence of the importance of extracortical pathways in learning has been reported from studies of animal conditioning in which the training was managed exclusively with direct electrical stimulation of sensory and motor areas in the cortex. After suitable pairing of sensory stimulation (CS) and motor stimulation (US), activation of the sensory electrode by itself led to the limb movement (now the conditioned response) that had occurred originally only when the motor electrode was stimulated (Doty 1961). Cutting transcortical connections between the two electrodes did not eliminate the conditioned response. That transcortical pathways are not necessary for such a newly developed neural circuit was further confirmed by studies in which similar electrophysiological conditioning was accomplished even though the sensory electrode was in one cerebral hemisphere, the motor electrode in the other, and the interhemispheric connections

(corpus callosum) completely severed (Doty & Giurgea 1961). While the cortex is certainly involved, in one way or another, in a variety of kinds of learned behavior, it appears to be substantially dependent on vertical interconnections that exist at all levels of the central nervous system.

Geography of the learning process

The recording of spontaneous EEG rhythms during simple learning situations, usually one form or another of classical conditioning, has shown that various parts of the brain are differentially active throughout successive stages of learning.

Alpha rhythm and alpha blocking. The use of brain wave changes to trace the shifts of brain activity during learning was initiated by an accidental observation of the French neurophysiologists G. Durup and A. Fessard in 1935. These investigators were studying the EEG alpha rhythm, a moderately slow wave form that can be recorded from the visual cortex of a resting animal during periods of reduced visual stimulation. This slow brain wave is arrested (alpha blocking) and replaced with a faster, lower voltage pattern following the onset of a bright light. This faster EEG pattern is what has since come to be known as the arousal pattern and, as discussed previously, is thought to indicate increased activity in the brain area concerned. Durup and Fessard were photographing examples of alpha blocking when they noticed that the click of the camera shutter started to induce the blocking even before the bright light was presented. They recognized that the click, by virtue of being paired with the light, had acquired the ability to influence the alpha waves. The conditioning-like properties of these paired sensory events attracted the attention of investigators throughout the world, and, with many modifications and elaborations, the study of spontaneous EEG changes during various conditioning procedures has since received widespread study (Morrell 1961a, pp. 444–451).

Localization of the arousal pattern. Early in conditioning, an EEG arousal pattern is seen widely throughout all levels of the brain. With further pairing of the conditioned and unconditioned stimuli, however, these generalized electrical changes start receding to areas, particularly cortical ones, that are related to the unconditioned stimulus and, finally, to areas concerned with the conditioned response. Since the arousal type of EEG is taken to mean that patterned or potentially integrating neural activity is taking place, widespread circuits apparently are active, or available, for use early in learning; as learning progresses, the cells and path-

ways involved become more localized along with the differentiation and refinement of the conditioned response.

Slow wave changes. During the early period of diffuse brain activity, a subcortical EEG arousal pattern has been particularly noted in the reticular formation and limbic system and is thought by some to be related to attentional and motivational priming of the central nervous system, preparatory to learning, when the organism finds itself facing a novel situation. Two Hungarian investigators, K. Lissák and A. Grastyán, reported (1960) a specific type of slow wave change (theta) in the subcortical hippocampus during learning. They believe that this change, which arises during early training and subsides shortly before conditioning is complete, represents a suppression mechanism that damps distracting activity, both neural and behavioral, during the time that the learned response is being developed. When conditioning is complete, the EEG arousal pattern is seen most consistently in those connections between the thalamus and the neocortex that are topographically appropriate to the final learned response.

"Tagged" brain-wave changes. Comparable findings have been reported recently from a similar, although slightly more elegant, experimental procedure in which tagged brain-wave changes, as they are called, are recorded during conditioning. In this type of study, a flashing or flickering light is used as the conditioned stimulus. If the flicker rate is not too divergent from the 10-per-second rate of the brain's alpha rhythm, EEG oscillations at about the same rate as the conditioned stimulus can be detected as they shift among different brain structures at various stages of the learning. While such a procedure was first reported about twenty years ago by M. N. Livanov and K. Poliakov in connection with a standard conditioning study, it has recently been put to more elaborate experimental use by the American research team of E. R. John and K. F. Killam (1960). These investigators recorded such frequency-specific EEG changes, as they are called, while cats were learning a differential discrimination problem in which two lights, flashing at different rates, were the positive and the negative stimulus. There were thus two frequency-specific changes to be sought in the brain wave record. The cats had to learn to perform an avoidance response to one flicker rate but not to the other. Under these conditions, the general sequence in which the tagged EEG changes appear in different brain structures during training was much the same as already discussed above. John and Killam, however, discovered one new phenomenon of con-

siderable interest. They found that when the flicker rate of the stimulus, and thus the tagged EEG rhythm seen in the visual cortex, matched the frequency of the EEG pattern recorded from certain subcortical structures, a correct response was more apt to be made. Discordance between the EEG frequencies at these two sites, on the other hand, was commonly correlated with either an error of omission or commission. It is as though the way the animal "reads" the stimulus or, for one reason or another, is "set" to respond to it is represented by the subcortical frequency, while the temporal events in the visual cortex are tied, of course, to the actual flickering stimulus being presented. The importance of an organism's expectancies or response set in conditioning situations is not a new idea (Sperry 1955), although it is presently receiving renewed consideration.

Evaluation of evidence. While these bioelectric events indicate something about the widely shifting focuses of neural activity that occur during the course of even a simple learning experience, there is no compelling reason to believe that EEG changes of the type just discussed, no matter how meaningful their localization may appear to be, represent electrical changes that are necessarily associated with stimulus recognition or the eventual fixation of memory. For example, when EEG arousal occurs in its immediate vicinity, an individual cortical neuron may show increased transmission of nerve impulses, decreased transmission, or neither (Jasper et al. 1960). While conditioning systematically brings about statistical changes in the activities of single cells in particular brain areas, an invariant relation between the occurrence of a conditioned response and activity in a specific neuron thus far has not been reported. It may be, of course, that the performance of even a specific learned response by a particular subject does not always involve precisely the same individual neurons.

The hippocampus and memory. Although much that we have considered indicates the diffuse nature of the neural substrate of learned behavior, scientists in several disciplines have become interested recently in the possibility that one subcortical structure, the hippocampus, contributes uniquely to the memory process. The hippocampus is in the rhinencephalon, the primitive portion of the forebrain. Recent interest in the hippocampus arose as the result of memory losses observed in human patients who had sustained damage to this brain structure as the result of either surgery or disease (Milner 1959). Such findings in man are particularly convincing since, in contrast to lower animals,

one can be more confident that the deficit is in memory per se and not in some performance capacity that simply leaves the animal subject unable to demonstrate what has in fact been remembered. These neurological patients show a striking loss of recent memory, particularly if they are distracted while trying to memorize or have had no chance for repetitious practice. Retrograde amnesia for as long as a year prior to hippocampal damage is also seen in people with this type of brain lesion.

While no details are known about the manner in which the hippocampus might contribute to memory, one group of investigators discovered that electrophysiological activity in the hippocampal area of the cat did differ with correct and incorrect choices in a maze (Adey et al. 1960). The majority of studies employing hippocampally damaged animals, however, have failed to find the expected loss in learning ability when the operated subjects were measured on discrimination tasks or conditioned avoidance tests. It could be, however, that the failure to demonstrate a memory loss in animals with hippocampal lesions is due to the fact that tests of animal learning are typically the type that measure learning across a series of practice trials. This is the kind of repetitious training that, based on human studies at least, might minimize evidence of the surgically produced memory deficit. This explanation receives some support from the fact that mice, with chemically induced hippocampal damage, showed dramatic losses of recent memory when they were tested with a very simple learning task that they could have mastered in only a few practice trials (Flexner et al. 1963).

Mechanisms of memory storage

A variety of behavioral experiments support the notion that the early and late stages of the process of memory fixation are probably based on different physiological mechanisms (Gerard 1961). There is an early stage, which lasts for less than an hour and is easily disrupted by a variety of physiological insults to the brain, such as lowering its oxygen supply, cooling it, or bombarding it with electric current (Glickman 1961). Thereafter, the memory trace, or engram as it is sometimes called, becomes more rigidly fixed and cannot be disassembled so easily. As already discussed, these facts are usually taken to mean that the first evanescent steps in memory fixation are electrical in nature and then subsequently become anchored in some biochemical or structural alteration, most commonly presumed to be at the synapse.

Aside from these two well-recognized stages of memory fixation, sometimes called the dynamic

and static stages of memory, there may be two additional critical time periods in the sequence of physical changes that underlie memory fixation. For one thing, chemical interference in the hippocampal area can eliminate a newly learned habit as long as a week after the original learning but not thereafter (Flexner et al. 1963). Finally, generalized brain trauma, such as a concussion, can disrupt the memory for events extending back for months and years prior to the injury. Yet, memory commonly remains intact for the stretch of years preceding this period of retrograde amnesia. There thus could be at least four successive steps in the process of memory storage: (1) an acute process, initiated at the time of learning and completed before an hour has passed; (2) a semiacute second process, at least in the hippocampal area, requiring some number of days; (3) a slowly developing third stage, completed over a period of months or years; and (4) a final, static stage of memory, which is not commonly open to disruption by either experimental or clinical influences. As Deutsch (1962) has pointed out, however, it is not clear that all these stages necessarily involve different physiological processes; they could represent, in part, different degrees of development in some common process. Finally, since it is not uncommon for the memories lost in retrograde amnesia to be retrieved when the patient recovers, it may well be that long-term memories are never really eliminated by generalized trauma to the brain but are only made unavailable for current use.

Dominant focus and postpolarization memory. In 1953, V. S. Rusinov discovered an electrophysiological procedure by which he was able to produce new temporary connections between sensory and motor cells in the cortex. He applied a mild anodal current to a small area of motor cortex in the rabbit and found, during this period of polarization, that a previously indifferent sensory stimulus, such as a novel tone, induced a discrete skeletal movement that was related topographically to the part of the motor area that was polarized. The polarizing current is thought to lower the excitability threshold of the motor cells that it influences and thus permit sensory activity in widespread brain areas to "drain," so to speak, through the polarized area and initiate motor activity appropriate to the polarized motor cells. Using a term originally suggested by A. A. Ukhtomskii in 1926, such an area of elevated excitability is called a dominant focus.

If a dominant focus is induced in the part of the motor area that, for example, initiates response pattern A (e.g., right foreleg flexion), the focus will help maintain previous conditioning if the con-

ditioned response was pattern A. On the other hand, a conditioned response of pattern B is suppressed by the induction of dominant focus A. Such findings suggest that something like a dominant focus might be involved during the early stages of conditioning. The effect of a dominant focus persists for about thirty minutes after the anodal current is removed (postpolarization period), which matches reasonably well the time course of the early dynamic stage of memory as it is reported by some workers.

Frank Morrell (1961b), an American investigator, studied the activity of individual motor cells within the area of a dominant focus and started to analyze the fiber pathways, which are critical for this interesting phenomenon. He demonstrated, further, a degree of specificity for the 30-minute "memory" in the area of a previous dominant focus; the motor area can be activated during this postpolarization period only by a stimulus that has been presented during the period of polarization. Both transcortical and subcortical pathways were found to be necessary for the activation of the dominant focus by an effective stimulus event. Finally, perseverating activity of nerve impulses was not detected during the postpolarization period in the area of the dominant focus. This is contrary to what might have been expected if reverberating circuits of nerve impulses were responsible for the short-term maintenance of memory in the area. If the short-term phase of memory really is electrical in nature, this finding suggests that the process might be based on persistent graded potentials rather than on propagated nerve impulses. It is still possible, of course, that the early memory process is based on some other fragile biological process, which is possibly chemical and which is not apparent to the recording electrode of the neurophysiologist.

RNA and long-term memory. The physical basis of long-term memory is no better understood than the case of recent memory. As we have seen, the most popular idea is that some permanent change of a structural, or at least chemical, nature takes place at the synapses, and thereafter the routing or patterning of nerve impulse transmission is altered. No specific structural change at a synapse, associated with learning, has ever been demonstrated experimentally. In recent years, however, there has been growing interest in the possibility that changes in the ribonucleic acid (RNA) molecules of the nerve cell might be responsible for structural changes, at the synapse or elsewhere, that could then serve the purpose of long-term memory. This possibility, suggested by Joseph J.

Katz and Ward C. Halstead in 1950, now has received some indirect experimental support, although definite proof of such a mechanism is still lacking (Dingman & Sporn 1964). The general idea is that patterns of neural activity, impinging on a particular nerve cell, would shape the structure of complex RNA molecules within the cell. The RNA, as a regulator of protein synthesis in the cell, would thereafter perpetuate chemically coded protein molecules, thus rendering the cell, for example, maximally sensitive to the temporospatial pattern of neural activity that had originally induced the structural change in the RNA (Hydén 1962). How electrical neural activity could modify the structural pattern of RNA or how structurally coded RNA might then influence the synaptic characteristics of its neuron is still entirely speculative. Nevertheless, changes both in the concentration of RNA and in the specific chemical structure of RNA have been demonstrated in specific brain centers that have been subjected to high levels of neural activity or, more interestingly, have been involved in the learning of new patterns of behavior.

VIII

VERBAL LEARNING

Research in the area of verbal learning is concerned with the experimental analysis of the acquisition and retention of verbal habits. The major emphasis in both experimentation and theory construction has been on rote learning, that is, the mastery of verbal materials in a prescribed arrangement. Studies of rote learning have provided the central body of empirical facts, analytic tools, and theoretical concepts dealing with verbal learning.

Historical developments

Early experimental studies. The first systematic experimental investigation of rote learning was carried out by the German psychologist Hermann

Ebbinghaus, whose treatise *Memory* (1885) occupies an undisputed position as a classic in the field. Ebbinghaus set out to show that higher mental processes such as memory could be studied under strictly controlled experimental conditions and that they could be precisely measured. His conception of the processes of learning and memory was heavily influenced by the British empiricist doctrine of association by contiguity. In a monumental series of experiments, which were carried out with himself as the only subject, Ebbinghaus introduced procedures and methods of analysis which provided the point of departure for the subsequent development of the entire area of verbal learning. The large majority of Ebbinghaus' experiments were concerned with the acquisition and retention of series of discrete verbal units. In an effort to develop standardized materials that could be used interchangeably in a large variety of learning tasks, Ebbinghaus devised the nonsense syllable as the unit to be used in the construction of verbal series. (A nonsense syllable is a consonant-vowel-consonant combination devoid of dictionary meaning.) While such materials turned out to be far from equal in difficulty, the introduction of these materials was the first step toward the standardization and classification of the verbal units used in studies of rote learning. To provide a uniform standard of attainment with respect to which differences among tasks and conditions of practice could be evaluated, Ebbinghaus established the concept of a criterion of performance, for example, the errorless reproduction of an entire series. The number of repetitions or the amount of time required to reach this criterion could then be related to such variables as the length of the series or the temporal distribution of practice periods. A fixed criterion of performance also made it possible to evaluate retention after the cessation of practice; specifically, Ebbinghaus measured the amount of retention in terms of the amount of time saved in relearning a series relative to the time required for original acquisition. Using these methods of analysis, Ebbinghaus established a number of basic principles of acquisition and retention. His findings included evidence that the amount of practice time per item increases with the length of the series and that a strong positive relationship exists between the number of repetitions of a task and the degree of retention. Another famous product of Ebbinghaus' investigations is the classical curve of retention, which is characterized by a steep initial drop in retention immediately upon the end of learning, followed by more gradual losses thereafter.

Ebbinghaus' approach was soon adopted in other laboratories, and additional techniques for the study of rote verbal learning were developed rapidly. Among the early German investigators, G. E. Müller deserves special mention. In Müller's laboratory the first systematic studies of the processes of interference in retention were carried out. He was also responsible for many refinements in experimental technique, such as the use of an automatic exposure device for the presentation of learning materials (the prototype of the contemporary memory drum). Within less than two decades after the appearance of Ebbinghaus' pioneer investigations, the study of rote verbal learning had become a standard procedure in laboratories of experimental psychology.

American functionalists. In the United States the development of the area of verbal learning is historically tied to the functionalist movement, which helped to make the experimental study of learning a central concern of contemporary experimental psychology and which emphasized the application of psychological principles to problems of education. Although those working in the functionalist tradition put the discovery of empirical laws ahead of formal theory construction, there was a strong predilection for the analysis of the learning process in terms of principles of association. A discussion of the influence of the functionalist movement on the psychology of learning is provided by Hilgard ([1948] 1956, chapter 10). The associationist orientation permitted a ready translation of theoretical concepts and experimental operations into the language of stimulus-response psychology, which became widely accepted under the influence of behaviorism. Thus, the prevalent approach to problems of verbal learning became that of an associationistic stimulus-response psychology. With some important exceptions to be noted later, there was no strong commitment to formal theories of behavior.

A pragmatic orientation is apparent in the writings of the experimental psychologists who had a major influence on the development of the field of human learning. An exposition of the prevailing theoretical approach was given in Edward S. Robinson's *Association Theory Today* (1932). The broad definition of *association* as "the establishment of functional relations among psychological activities and states in the course of individual experience" (p. 7) was designed to accommodate the pursuit of a wide range of empirical questions within a common associationist framework. Robinson stressed the multiplicity of the laws of association and the necessity of reformulating such

laws as functional relations between these multiple antecedent conditions on the one hand and measures of associative strength on the other.

The emphasis on functional relations led to the formulation of a program of *dimensional analysis* as a guide to experimental investigation. The essential objectives of such a program were first outlined by McGeoch (1936); a later systematic exposition of this approach may be found in an important article by Melton (1941). Learning situations vary continuously with respect to a manifold of descriptive characteristics or dimensions, and learning tasks can be ordered along these dimensions to provide the framework for the exploration of quantitative functional relations. Among the major axes of reference is the verbal-motor dimension; purely verbal tasks define one extreme and predominantly motor ones the other. A second dimension is defined by the degree to which the subject must discover the correct response and ranges from the acquisition of rote series to problem-solving situations. A third dimension refers to the degree to which mastery of a task requires a response to relational rather than to absolute properties of the stimuli.

Influence of conditioning theory. While dimensional analysis has provided a thread of continuity in empirical research, there have been important attempts to conceptualize the facts of verbal learning within the framework of general psychological theory. During the period between the two world wars an important landmark was the publication of the *Mathematico-Deductive Theory of Rote Learning* by Clark L. Hull and his associates (1940). In this analysis, the basic phenomena of serial rote learning are deduced from a set of postulates that were derived largely from the theory of classical conditioning. The effective strength of the associations linking the members of a verbal series was conceived as representing the balance of excitatory and inhibitory potentials, in accord with the dual-process interpretation of Pavlovian conditioning. With the aid of assumptions about the conditions governing the growth and decline of excitatory and inhibitory tendencies, specific quantitative predictions were made concerning the shape of the serial-position curve (level of performance as a function of the position of an item in a series), the effects of the temporal distribution of practice trials, and other properties of serial learning. Some of these predictions were confirmed experimentally; however, the scope of the theory is limited, and its influence has been declining with the rapid accumulation of empirical findings that fall outside its boundary conditions.

Another systematic application of principles of classical conditioning to verbal learning was proposed by Eleanor J. Gibson (1940). Gibson's analysis centered on the concepts of stimulus generalization and differentiation, which were adopted from conditioning theory. Stimulus generalization refers to the tendency for the conditioned response to be elicited by stimuli similar to the conditioned stimulus. The amount of generalization describes a gradient, that is, it is directly related to the degree of similarity between the training stimulus and the test stimulus. Differentiation refers to the reduction of generalization as a consequence of reinforcement of responses to the training stimulus and nonreinforcement of responses to other test stimuli. According to Gibson's analysis, speed of acquisition is determined by the rate at which differentiation among the stimulus items is achieved during practice. Thus, speed of learning should vary inversely with the degree of interstimulus similarity. In general, the experimental facts are consistent with this prediction. The theory also predicts, in accordance with principles of conditioning, that generalization tendencies recover spontaneously over time, with a consequent loss of differentiation. It follows that long-term retention, like speed of acquisition, should vary inversely with interstimulus similarity. However, this prediction has consistently failed to be confirmed. This lack of support for one of the critical deductions from the theory necessarily calls into question the validity of the basic postulates. The analytic power of the theory is also limited by the failure to consider the role of response generalization along with that of stimulus generalization. A comprehensive evaluation of the theory, which has exerted considerable influence on research in verbal learning ever since its publication, is provided by Underwood (1961).

Gestalt psychology. Although there has been wide agreement among investigators of verbal learning on the usefulness of associationist concepts in the formulation of empirical questions and theoretical issues, such agreement has been by no means general. A quite different approach is represented by exponents of the gestalt school of psychology, whose work in verbal learning was directed primarily at the validation of general principles of their theory. An exposition of this approach may be found in Koffka (1935, chapters 10-13). From the point of view of gestalt theory, learning and retention are governed by the same principles of organization that govern the formation of perceptual units. In the acquisition of verbal tasks, relationships such as similarity and

proximity between the component items are considered critical in determining the readiness with which the organization required for mastery is achieved. The organizations developed during learning are, in turn, assumed to be preserved in the nervous system as memory traces, whose subsequent development is likewise governed by principles of organization. Re-exposure to part of an organized pattern activates the trace of the pattern and thus permits the recall of other component parts. Association is, therefore, interpreted as a special case of organization. Experimental studies initiated by gestalt psychologists have sought to demonstrate the applicability to verbal learning and memory of principles of perceptual organization. An example is provided by the studies of the effects of perceptual isolation. When a unique item is embedded in an otherwise homogeneous series, the unique or "isolated" item is recalled better than the average member of the homogeneous series. According to gestalt theory, the traces of the homogeneous items suffer assimilation and lose their identity, whereas the trace of the unique item remains distinctive and accessible. This dependence of recall on the relationship between items is interpreted as analogous to the salience of a perceptual figure against a homogeneous background. Alternative interpretations have been offered, for example, the differential susceptibility of isolated and homogeneous items to generalization. The conditions determining the isolation effect are still under investigation. This example illustrates the fact that crucial experiments permitting a clear-cut decision between gestalt and associationist interpretations have often been difficult to design. [See GESTALT THEORY.]

Recent developments. The two decades since the end of World War II have witnessed a rapid growth of activity in the field of verbal learning, with several new developments adding greatly to the diversity of experimental methods and theoretical concerns. Perhaps the most important trend is the convergence on common problems of research in psycholinguistics and in verbal learning. This development is reflected in the increased emphasis on the role of natural language habits in the analysis of verbal learning. A large amount of work has centered on the assessment of the effects on acquisition and retention of the associative hierarchies that are developed through linguistic usage. The method of free association (in which the individual is required to respond to each stimulus word with the first other word that comes to mind) and related normative techniques have been used to determine the structure of verbal associations

characteristic of a given speech community. Learning tasks constructed on the basis of such norms are then used to evaluate the influence of pre-existing associative patterns on the formation of new verbal habits. Within this problem area a focus of special concern has been the study of mediational processes, that is, of the ways in which pre-existing associations serve to facilitate the establishment of connections between initially unrelated terms (see Jenkins 1963). The influence of contemporary linguistic analysis is also reflected in the growing number of investigations concerned with the role of grammatical habits in the acquisition and performance of verbal tasks. Largely under the influence of George A. Miller (e.g., 1962), much of the recent work has been directed at the exploration of the psychological processes suggested by the principles of transformational grammar.

In the experimental study of memory processes, several influences have converged to produce an upsurge of interest in short-term retention. Any *a priori* distinction between short-term and long-term memory is, of course, arbitrary; in practice the operational difference is between retention intervals of the order of seconds or minutes on the one hand and of hours, days, or weeks on the other. Rapid developments in the theory of communication and in the study of man-machine interaction have brought to the fore the question of man's capacity to process and to store continuously changing inputs of information; for example, in the performance of monitoring tasks incoming information has to be retained for critical periods of time to permit effective action. Thus, the study of short-term memory is an integral part of the analysis of the nervous system as a limited-capacity channel for the transmission of information. This general approach is well represented by the work of Broadbent (1958), who has introduced a number of influential new techniques for the measurement of short-term memory. The availability of the analytic methods of information theory has, of course, been of considerable value in bringing order to measures of immediate memory that are obtained with a wide variety of materials. Short-term memory also has continuing systematic significance for theories of the physiological basis of memory. A central concept of several influential theories is that of a transitory memory trace, which is assumed to fade or decay rapidly unless it is restored by repetition or rehearsal. The assumption of a short-lived immediate trace is characteristically supplemented by the postulation of a separate and distinct mechanism of long-term

storage. A considerable amount of effort is being devoted to experimental tests of the dual-process conception. A systematic question on which agreement does not appear to be in sight as yet is whether the principles governing short-term and long-term memory are continuous or discontinuous. [See FORGETTING.]

Recent developments in verbal learning, as in several other special fields of psychology, include the construction of mathematical models for the description of circumscribed sets of data. Among the most influential approaches have been the stochastic models that treat acquisition as a probabilistic process. Very briefly, it is assumed that on any given learning trial (a) the organism samples the environmental events which constitute the stimulus situation; (b) all the stimulus elements sampled become connected to the response occurring contiguously with them; and (c) such association by contiguity occurs in an all-or-none fashion, that is, reaches maximal strength on a single trial. The probability of occurrence of the response increases as more and more stimulus elements are connected with it. While the most important applications of these models have been to discrimination learning and conditioning, the models have also been used for the acquisition of verbal associations as well. A point of major theoretical significance is the assumption made by stochastic models that association by contiguity occurs in an all-or-none fashion. If verbal stimuli function as single elements, it follows that associations are not built up gradually as a function of practice but, instead, change in probability from zero to one after a single occurrence. The assumption that associations may vary continuously in strength and are built up gradually through practice has been explicit or implicit in associationist interpretations of verbal learning. This assumption, which has been designated as the incremental hypothesis, has been challenged in recent years by exponents of the all-or-none position. Experimental tests to decide between these alternative conceptions have focused on the question of whether there is a growth in associative strength on practice trials prior to the first correct response. While it is fair to say that the evidence thus far has favored the incremental position, the issue cannot be regarded as finally settled (for a review see Postman 1963). The emergence of this controversial issue illustrates the recent trend toward the consideration of hypotheses about the nature of association and memory in the context of studies of verbal learning. [See MODELS, MATHEMATICAL.]

A brief survey of some representative experi-

mental methods and findings in the area of verbal learning now follows. The evidence is grouped under the headings of acquisition, transfer of training, and retention. Detailed reviews and discussions of the relevant literature may be found in McGeoch (1942) and in the collections of papers edited by Cofer (Conference on Verbal Learning . . . 1961), Cofer and Musgrave (Conference on Verbal Learning . . . 1963), and Melton (Symposium . . . 1964).

Acquisition

It will be convenient to consider the analysis of the process of acquisition with reference to specific experimental procedures, each of which focuses on a different type of verbal performance.

Paired-associate learning. In the paired-associate method, the subject's task is to learn a prescribed response to each of a list of stimulus terms (much as in vocabulary learning). The characteristics of the stimulus and response terms can be varied independently. An important analytic advantage of the method is, therefore, that it permits the assessment of stimulus and response functions in the acquisition of associations. Progress in this task will depend on the extent to which the following requirements are met: (a) the stimulus terms are differentiated from each other; (b) the prescribed responses are available as integrated units in the subject's repertoire; and (c) stable associative connections are developed between the appropriate stimulus and response terms.

It is apparent that the requirements of the task with respect to the stimulus and response terms are not the same. Whereas the response terms must be recalled as prescribed, the stimulus terms need only be discriminated from each other and recognized as the occasions for the performance of the appropriate responses. The subject is free, therefore, to attend to only those characteristics of the stimulus which are minimally essential for the placement of the correct responses, that is, the subject can practice "stimulus selection." Recognition of this fact has led to the distinction between nominal and functional stimuli (Underwood 1963). The nominal stimulus refers to stimulus terms as specified by the experimenter for presentation to the subject; the functional stimulus refers to those characteristics of the stimulus which actually function as cues for the learner. The available evidence indicates that stimulus selection does, in fact, occur within the limits permitted by the requirements of the task; for example, when the stimulus is a compound composed of elements which vary in meaningfulness, there is a strong

tendency to select the more meaningful element as the functional cue.

The analysis of the components of the paired-associate task makes it useful to conceive of the total acquisition period as divided into two successive stages, namely, a response-learning stage and an associative stage (Underwood & Schulz 1960, pp. 92-94). During the former, the prescribed responses are established as integrated units available for performance; during the latter, the responses are linked to the appropriate stimuli. If the responses are items in the subject's pre-experimental repertoire, for example, familiar words, the response-learning stage reduces to a response-recall stage during which the subject learns to restrict his responses to the units in the list. The two stages certainly overlap in time. The distinction is, however, useful in the analysis of the conditions which influence performance in paired-associate learning.

Of the task variables which influence speed of acquisition, two will be singled out on the basis of the magnitude and reliability of their effects. These are (a) meaningfulness and (b) intralist similarity. In current usage, the term "meaningfulness" refers to several scaled characteristics of verbal units, such as the probability of a unit evoking an association within a limited period of time, the number of different associations evoked by the unit, etc. These indices tend to be closely related to each other and to the frequency of occurrence of the unit in the language (for a survey of measures of meaningfulness see Underwood & Schulz 1960). Intralist similarity may be either formal or semantic. Formal similarity is defined by the degree to which overlapping elements, such as letters, are used in the construction of different units included in a list; this variable is characteristically manipulated in lists composed of nonsense items. Semantic similarity refers to the degree of synonymy and applies to lists composed of words.

Meaningfulness. The speed of paired-associate learning varies widely as a function of meaningfulness, but the relationship is much more pronounced when responses rather than stimuli are varied in meaningfulness (Underwood & Schulz 1960). From the point of view of the two-stage analysis of acquisition, it is clear that meaningfulness decisively influences the response-learning stage: the more fully a response unit conforms to prior linguistic usage the more readily it enters into association with new stimuli. There are two factors which may serve to reduce the effectiveness of the variable of stimulus meaningfulness: (a) stimulus selection may counteract the differences

that exist in the nominal stimuli; (b) increases in stimulus meaningfulness may facilitate not only the formation of associative linkages with the prescribed responses but also the development of inappropriate associations with other responses. Thus, associative facilitation and interference may increase concurrently as a function of stimulus meaningfulness.

Intralist similarity. The effects of intralist similarity also differ depending on whether stimuli or responses are manipulated. In general, speed of acquisition varies inversely with the degree of similarity of the stimulus terms. As stimuli become less discriminable, the associative phase of learning is retarded. Variations in response similarity, on the other hand, have only small effects on the rate of learning, except for units of low meaningfulness. The usual absence of a large effect is attributable to the balance between two opposed influences: As responses become more similar, the amount of response learning is reduced; at the same time, individual responses become less discriminable from each other and the associative phase is prolonged.

Serial learning. Serial-learning tasks require the reproduction of a series of items in a prescribed order. The experimental procedure typically consists of the paced presentation of the successive members of the series, with the subject required to anticipate each item before it appears. Speed of acquisition varies reliably as a function of the ordinal position of the item in the series. The initial items are usually acquired first, the terminal items next, and the central items last. Thus, when percentage of correct responses during learning is plotted against serial position, a typical bow-shaped curve is obtained. Classical interpretations of serial learning (for example, that of Hull mentioned earlier) were based on the assumption that an individual member of the series serves a dual function during acquisition: it is the response to the immediately preceding item and the stimulus for the immediately following one. The bow-shaped serial position curve was attributed to interferences from incorrect associations among nonadjacent members of the series. Given certain assumptions about the number and strength of such remote associations, it can be shown that the total amount of interference should first increase and then decrease as a function of serial position. Recent experiments have, however, served to call the classical conception of serial learning into question. Some of the critical evidence comes from experiments in which the subject first learns a serial list and immediately there-

after a paired-associate list in which the pairs are composed of adjacent members of the serial list. If the mastery of the serial list depends on the establishment of a chain of sequential associations, pronounced facilitation should be found in the acquisition of the paired-associate list. A conclusive test of this prediction has proved difficult. Performance on the critical transfer task appears to be complexly determined and sensitive to procedural variations. The difficulties encountered by the classical hypothesis have raised questions about the nature of the functional stimulus in serial learning; for example, it has been suggested that each member of the series is associated to its ordinal position in the series rather than to the preceding item. This problem is receiving considerable experimental attention at the present time (Underwood 1963).

Free learning. The two methods discussed above require the establishment of prescribed links between verbal units, and, thus, they focus on the development of sequential associations. By contrast, the method of free learning yields information about the ordering and reproduction of verbal units when no sequential constraints are placed upon the subject. Under this method, a list of items, such as words, is presented to the subject, and he is then permitted to reproduce them in whatever order they occur to him (free recall). The method is useful in the investigation of pre-experimental habits of classifying verbal units and of the process of recall (for general discussions see Deese 1961; Postman 1964). The major determinants of the amount of free recall are (a) the total learning time prior to the test of recall and (b) the number and strength of the pre-experimental associations between the units in the list. The total learning time is the product of the list and the presentation time per item. The number of items recalled after a single exposure of a list remains approximately invariant with total learning time, that is, the number of items recalled increases with the length of the list and with the amount of study time per item, but a decrease in the value of one of these variables can be compensated for by an increase in the other. Thus, it is the total amount of time available for practice which is critical rather than the length of the task or the exposure rate per se. With length and rate held constant, the number of words recalled varies with the average degree of associative connection between the items in the list (as determined, for example, by the method of free association). In the absence of external constraints, recall performance reflects pre-exist-

ing associations and relations between the component units of the list. As free learning continues beyond a single presentation and recall, stable groupings of items are likely to be formed which are carried over from one test of recall to the next.

Transfer of training

Transfer of training refers to the influence of prior learning on the acquisition of new habits. The transfer effects may be positive or negative, depending on whether the earlier training facilitates or inhibits the mastery of the later task. In studies of verbal learning it has been conventional to distinguish between specific and general transfer effects. Specific transfer effects are those attributable to known similarity relations between successive tasks; general transfer effects represent the development of skills which cannot be ascribed to known similarity relations between tasks. General effects will be considered first.

General effects. When unrelated verbal lists are learned in the laboratory, the speed of acquisition typically increases, sharply at first and more gradually thereafter. Such progressive practice effects have been demonstrated for both paired-associate and serial learning. When learning sessions are held daily, the gains in performance are considerably greater within sessions than from one session to the next. A common interpretation of this finding is that the gains within a session are largely a matter of warm-up, that is, the development of postural adjustments, rhythms of responding, and other components of a set appropriate to the learning task. Such adjustments to the requirements of the task may be expected to be lost once the subject leaves the experimental situation. The changes which persist from one session to the next are attributed to "learning-to-learn," that is, the acquisition of higher-order habits or modes of attack which are relatively stable and persistent. According to this analysis, warm-up both develops and declines more rapidly than do the habits which constitute learning-to-learn. The possibility cannot be ruled out, however, that perceptual-motor adjustments are conditioned to the experimental situation and that components of learning-to-learn are forgotten.

Specific effects. The principles of specific transfer have been investigated primarily as a function of the similarity relations between the stimulus terms and/or the response terms of successive tasks. One general principle is that the amount of transfer, whether positive or negative, increases as the stimulus terms in successive tasks become more similar; stimulus identity is, therefore, the

condition of maximal transfer. At a given level of similarity, the sign (positive or negative) and degree of transfer vary with the similarity, or strength of pre-existing associative connection, between successive responses. A large array of experimental findings may be subsumed under the following general principle: as the responses become increasingly dissimilar, the transfer effects shift from positive to negative. Thus, positive transfer is obtained when the successive responses learned to identical or similar stimuli are associatively related; negative transfer results when new unrelated responses are learned to old stimuli. These principles are, however, subject to modification by other factors, such as the readiness with which successive tasks can be differentiated from each other. For example, when old stimuli and old responses are re-paired, there is considerable negative transfer; even though the repertoire of responses remains the same, the identity of both stimuli and responses makes differentiation between successive tasks extremely difficult (for a discussion of methods and designs in the study of transfer see McGeoch 1942).

Retention

Retention refers to the persistence over time of changes produced by practice. It is apparent that retention is an integral component of acquisition; a habit can be mastered only if there is retention from one practice trial to the next. In the present context, however, the term retention refers to measurements of performance which are made after the end of a period of formal practice. The operational distinction between measures of acquisition and of retention is a convenient and, indeed, an essential one for investigation of the conditions of forgetting. The amount of retention is, of course, always inferred from specific measures of performance; the absolute level of performance will vary with the specific method of testing. Thus, after a given amount of practice, tests of recognition usually yield higher retention scores than do tests of recall, although the degree of discrepancy may vary widely as a function of the specific conditions of recall and recognition.

The basic empirical fact which theories of retention have sought to account for is the progressive decline in performance that occurs as a function of time after the end of practice. The position now held most widely attributes forgetting to the interference that develops between successively learned habits. Two major types of interference are distinguished, namely, retroactive inhibition and proactive inhibition. Retroactive inhibition

refers to the interference produced by the acquisition of new habits between the end of practice and the test of retention; proactive inhibition occurs when earlier habits interfere with the retention of a more recent task. In both cases, the amount of interference varies with the similarity relations between successive tasks; specifically, the amount of interference is governed by the same conditions of intertask similarity as is negative transfer. Thus, negative transfer in acquisition, retroactive inhibition, and proactive inhibition are complementary manifestations of habit interference. Retroactive and proactive inhibition differ with respect to the development of interference effects over time. Whereas retroactive inhibition is present to its full extent immediately after acquisition of the interfering task, proactive inhibition develops gradually over time. Several specific mechanisms responsible for the observed interference effects have been identified experimentally. These include (a) the unlearning, in the sense of reduced availability, of old associations during the acquisition of new ones; (b) competition between incompatible responses at the time of recall which may cause performance to be blocked or a dominant error to displace a correct response; and (c) failure to differentiate between the members of alternative response systems at the time of recall (for a review of interference theory see Postman 1961).

The principles of retroactive and proactive inhibition have been established in experimental situations in which the conditions of interference can be fully controlled. Interference theory assumes that the same principles apply to forgetting outside the laboratory. For example, the forgetting of a verbal task would be attributed to interference from other verbal habits acquired both prior and subsequent to that task. Proactive inhibition is likely to play a larger role than retroactive inhibition to the extent that the number and strength of prior habits exceed those of subsequent habits.

Regardless of theoretical interpretation, certain facts about the long-term retention of verbal tasks are well supported by the experimental evidence. The single most important determinant of the amount of long-term retention is the degree of original learning, with resistance to forgetting a direct function of the degree of overlearning. It is essential, therefore, to hold the degree of original learning constant whenever the influence of other variables, such as meaningfulness or intra-task similarity, on retention is to be evaluated. The evidence available thus far shows that the effects of such variables are minor relative to the sheer

degree of original learning. The practical implication is that overlearning provides the most certain means of insuring the long-term stability of verbal habits.

IX TRANSFER

The phrase "transfer of learning," or "transfer of training," refers to a class of phenomena that are aftereffects of learning. When some particular performance has been learned by an individual, the capability established by that learning affects to some extent other activities of the individual. The effects of the learning are said to transfer to these other activities. Having learned some performance, the individual may thereby be enabled to exhibit some additional, different performance that he could not do prior to learning. As more commonly used, transfer of training means that the individual is able to learn something else more readily than he could prior to the original learning (positive transfer) or that he is able to learn something else less readily than he could before the original learning (negative transfer).

Transfer of learning, since it is virtually always present as a learning effect, may reasonably be considered an essential characteristic of the learning process. Accordingly, it may be shown to play a role in a wide variety of human activities, includ-

ing the learning of language, social customs, values, and attitudes and the acquisition of the human skills and knowledge that underlie practically all types of vocational activity. Transfer of learning is of particular importance in formal education. In the opinion of many educators, education should have transfer of learning, or "transferability of knowledge," as a recognized goal. It is generally agreed that the assessment of outcomes of education and training should include measures of transfer in addition to more direct measures of learning.

In studying the phenomenon of transfer of learning, investigators have employed a wide variety of situations and techniques. The work of experimental psychologists includes the exploration of such questions as (1) the degree of transfer resulting from the establishment of conditioned responses; (2) the specificity and limitations to transfer in the learning of simple perceptual and motor acts; (3) the occurrence of transfer between learned actions performed by different body members, such as the hand and foot; (4) the extent of bilateral transfer, as between actions performed by the left and right hands; (5) the occurrence of positive and negative transfer (called interference) in connection with the learning of verbal associates and sequences; (6) the positive transfer to a variety of specific novel situations resulting from the learning of principles; (7) the acquisition of a capability for transfer to novel discrimination problems in monkeys and human beings; and (8) the relation of transfer to the mediating effects of language in children. An interesting line of investigation has been undertaken by neurophysiologists in determining the conditions of transfer of training in animals with "split brains."

Educational aspects. In the field of educational research, studies have been concerned with the broad question of transfer of learning among the component subjects and topics that make up the school curriculum. Older studies arose from controversies over the doctrine of formal discipline, which held that certain subjects of the curriculum, such as Latin, geometry, and logic, derived a great part of their value from the general (that is, transferable) discipline they imparted to the mind, thus facilitating the learning of other subjects (Thorndike 1924). While this doctrine is probably quite true in the sense that certain capabilities acquired in school are much more widely transferable than others, the rationale for the choice of particular subjects was not a convincing one. At any rate, educational studies in the older tradition were concerned with such questions as whether transfer

of training could be measured from the study of Latin to the study of English or from that of geometry to other fields necessitating the use of logical thinking.

More modern studies of educational transfer have concerned themselves with such questions as the extent to which certain kinds of within-subject learning transfer positively to advanced topics, such as the concept of the numberline to later mathematical topics, the discrimination of language sounds to the learning of foreign language utterances, etc. Additionally, there has been concern with the possibilities of negative transfer between the learning of such activities as the formal statements of verbal definitions and the later learning of advanced mathematical principles and between the learning of letter sounds and the acquisition of reading skill. Finally, there is an increasing interest in the exploration of the possibility of designing instruction to develop such highly transferable individual characteristics as thinking strategies, curiosity, and even creativity.

Observing and measuring transfer

The simplest observations of transfer of learning occur in the following ways. The individual is known to have learned a new performance, such as spelling the word *nation* in response to the oral direction, "Spell nation." It may now be found that the same child is able to learn to spell such words as *motion* and *lotion* much more rapidly than he learned to spell *nation*. The inference is that the child learns to spell *motion* more rapidly than he would have if he had not first learned to spell *nation*. Besides the specific outcome of the original learning, the performance of spelling *nation*, there has been another aftereffect of learning: some residual capability, which shows itself in the speeding up of the learning to spell a different word. A different example, illustrating negative transfer, is the following. An individual has moved to a new location and must learn two new telephone numbers, those of his office and his home. One is 643-2795, and the other is 297-6534. He has learned single telephone numbers previously, without a great deal of difficulty. But he now finds that he makes many errors in trying to learn these two numbers, tending to substitute one portion of one number for another portion of the other number. Over a period of time, he finds that, in his experience, learning these two new numbers turns out to be more than twice as difficult as learning any one number has been. There appears to be interference between the two learning tasks; in other

words, the inference is made that the learning of one number produces a negative transfer effect, which slows down the attainment of recalling the other number.

Design of transfer experiments. While neither of these sequences of observation and inference is unreasonable, it is apparent that certain variables are uncontrolled, and this generates a requirement for a more painstaking method of observing transfer in an experimental sense. Returning to the example of learning to spell, it is clear that for any given individual we do not really know how long it should take him to learn to spell either *nation* or *motion* because we do not know where learning begins. Possibly some peculiarity of his past learning makes *nation* a difficult word and *motion* an easy one. Accordingly, an experimental design for the measurement of transfer typically includes a pretest to measure the initial capabilities of the individual before learning begins. Still another possibility must be considered: perhaps the increase of facility at the second task (spelling *motion*) is engendered partly by increased motivation, partly by a "set" to learn, or partly by "warm-up" factors (Thune 1950), rather than by the specific effects of learning the first task (spelling *nation*). As a consequence, it is usually considered necessary to include in a transfer experiment a control condition for this set of "general" factors.

The typical schema for experimental study of transfer that results from these control requirements is one that uses two groups of individuals, either assumed or shown to be equivalent at the beginning of learning. Table 1 provides an example.

Table 1

Transfer group	Control group
1. Takes pretest on task 2	1. Takes pretest on task 2
2. Learns task 1	2. Learns a task of a sort very different from tasks 1 and 2 but requiring the same amount of time as task 1
3. Learns task 2	3. Learns task 2

When this design is used, an average difference in the ease of learning (often, the time to learn) of task 2 in the two groups is taken to be an indication of "specific" transfer of training from the learning of task 1 to the learning of task 2. This and other experimental designs for the study of transfer are discussed by Murdock (1957).

Quantification. The amount of transfer of learning is usually expressed as a percentage (Gagné et al. 1948). Should it be found that a second performance is learned no more readily

than if the learning of a first performance had never occurred, transfer is said to be zero, or 0 per cent. If the second performance is found to be fully learned after the first performance has been learned, transfer is 100 per cent. Amounts between these extremes are, of course, often found. It is also possible to express negative transfer in this way; if a second performance takes half again as long to learn following initial learning of a first performance, the amount of transfer can be expressed as -50 per cent. The use of percentages in expressing amount of transfer is, however, largely a matter of convenience and has no particular systematic significance for an understanding of the phenomenon.

Conditions of positive and negative transfer

The occurrence of transfer of training depends, by definition, on the occurrence of previous learning. For certain performances, such as the learning of a set of verbal associates, the evidence indicates that the amount of positive transfer obtained is directly related to the amount of initial learning (Gagné & Foster 1949; Mandler & Heinemann 1956). As for negative transfer, a somewhat more complex relationship has been found to hold: the amount of interference exhibited in the second task increases as the amount of practice on the initial task is increased to some intermediate amount (McGeoch 1952, pp. 335-339). As practice of the initial task continues, however, the interference with the second task decreases and may under some conditions come to yield positive transfer (Mandler 1954).

Effects of similarity. As a general rule, the amount of transfer (positive or negative) is influenced by the similarity of the performance initially learned to the second performance in which the occurrence of transfer is observed. For example, when a conditioned response is established to a tone of 1,000 cycles, the amount of positive transfer exhibited to tones differing in pitch from this original stimulus bears a direct relation to the degree of physical similarity of the second tone to the original one (Hovland 1937). According to Gibson's study (1941), when the two performances are such that negative transfer is found, the amount of such interference increases with the degree of similarity between the stimuli of the first and second tasks. There is an apparent paradox to these findings, whose resolution seems to depend upon a careful definition of what aspects of the two performances are being compared in similarity. According to Osgood (1949), the prediction of the

direction of transfer (positive or negative) depends upon the differential specification of the stimuli of the two tasks and of their responses. A brief and partial summary of Osgood's conclusions may be given as follows. When tasks 1 and 2 contain identical responses, transfer is increasingly positive as the similarity of the stimuli of the two tasks increases. When tasks 1 and 2 contain identical stimuli, transfer is increasingly negative as the similarity of the responses of the two tasks decreases.

Despite the clarifying analyses that have been made, it is nevertheless apparent at the present time that the relation of transfer to the similarity of learned performances remains a perplexing and essentially unsolved problem. Two practical situations may serve as bench marks in consideration of what has yet to be understood about this relationship. (1) An individual first learns to drive a standard-shift automobile with the gearshift attached to the floor. A later model car comes equipped with the same type of transmission but with the gearshift attached to the steering column, so that first gear is now down rather than back, second gear is now up rather than forward and so on. Under these circumstances of apparent difference, the two tasks would nevertheless be judged as similar by almost any driver, and in fact the amount of positive transfer is close to 100 per cent. (2) The second situation is one in which a later model car comes equipped with a four-speed transmission; the gearshift, which is on the floor, must be pushed forward for first gear, backward for second gear, and so on. The situation in the second task is not only dissimilar; it may also be judged to have in it certain elements of reversal relative to the first task. It is a common experience that a considerable amount of negative transfer occurs under these conditions. Reversal of stimulus-response relationships has also been shown in laboratory tasks to produce large amounts of negative transfer (Lewis & Shephard 1950).

Mediational processes. Other limitations of the similarity principle in its present state of development are also shown by studies in which the performance acquired depends upon the learning of a mediational process.

Concept formation. The studies of Kendler and Kendler (1961) have shown that the performance of seven-year-old children who are required to learn a reversal of a discrimination task is markedly superior to the performance of four-year-olds on the same reversed task. These findings suggest that transfer occurs to the second task, which is dis-

similar to the original task to the extent of requiring an opposite choice (the choice of a white square as opposed to a black one), because the older children are able to provide an implicit verbal mediator (such as "the opposite"); whereas the amount of transfer for the younger children is very small because they are unable to do this. Logically related are Harlow's studies of learning in monkeys (1949). These animals, over many practice periods, were able to acquire the capability of choosing "the odd one" of three objects, even though the particular objects used may have been highly dissimilar in physical appearance to those used during the original learning.

Acquisition of principles. The importance of mediational processes for transfer of training is also illustrated by a number of studies concerned with transfer of principles. Principles, whether verbally stated or not, relate classes of stimuli to classes of performance; accordingly, they remove the control of performance from the specific stimuli of the situation. If a principle is learned in connection with some particular performance, then it is to be expected that this principle will make possible broad transfer to an entire class of problem situations. In connection with card-trick and matchstick problems, as well as with other tasks, Katona (1940) showed that the acquiring of principles led to high degrees of transfer to classes of problems that differed from those of original learning in physical appearance. In contrast, learning to solve the original problems without acquiring such principles resulted in only small amounts of transfer to new problems. One meaning of "teaching for transfer" in educational settings appears to be the encouragement of principle learning as opposed to rote learning on the part of pupils.

Mechanisms of transfer

Although referred to by a single class name, it is fairly certain that the various phenomena called transfer of training represent several different kinds of events. The differences among them are to be found in the specific conditions that generate them and, consequently, in the kinds of mechanisms that may be inferred to account for them.

Stimulus generalization. When a conditioned response is established to a signaling stimulus, it is found that the same response, diminished in frequency or strength, is given to other stimuli differing from the initial one along some physical dimension. This finding, the phenomenon of stimulus generalization, has been obtained many times, and the previously cited results of Hovland (1937)

are typical. The underlying mechanism in this case appears to be a fairly dependable characteristic of the functioning central nervous system. The effects of stimulation on the nervous system are not highly specific but are generalized. The amount of this generalization may be markedly reduced by further conditioning contrasting stimulation that is positive in its effects with stimulation that is negative, a procedure referred to as discrimination training.

Transfer in associative learning. An association of words like *ready-joyful* or *small-klein* is frequently described by psychologists as an S-R (stimulus-response) association, in which the first member of the pair is called the stimulus member; through learning, this first member comes to elicit the second, or response, member. This form of learning has an extensive literature of its own that cannot be thoroughly summarized here (see McGeoch 1952; Underwood 1964). The following conclusions, which come from these investigations, however, have particular relevance to the phenomenon of transfer of training and to suggested underlying mechanisms.

One of these conclusions is that under many conditions, positive transfer occurs in the learning of verbal associates when previous learning "predifferentiates" the stimulus members (Gibson 1940; Gannon & Noble 1961). A second finding is that positive transfer is also a common occurrence when the response members of the paired associates have been made familiar through previous learning (Underwood & Schulz 1960). The mechanism of transfer suggested by these two findings is that the learning of paired associates is *not* simply a matter of associating an S and an R; it is better conceived as the "linking" of two performances, the first of which may be called "recognizing the stimulus member" and the second "uttering the response member." The thorough learning of these two different performances apparently transfers positively to the subsequent learning of the completed linking, or "association."

A third finding throws additional light on the process of association. Positive transfer in paired-associate learning is generated by previously learned mediating responses, which appear to serve the function of "coding" the stimulus member into the response member (McGuire 1961; Jenkins, 1963). The associate *hand* to the French word *main* may, for example, be mediated by the previously learned word *manual*. Still a third kind of previously learned performance, then, appears to be responsible for positive transfer; the ease of

learning pairs of associates is markedly affected by the prior learning of what may be called a "coding performance."

The fourth conclusion that may be drawn from studies of associative learning has, in one form or another, been the subject of hundreds of experimental investigations. Negative transfer (interference) results when the learning of a pair of associates A-B is followed by the learning of the pair A-C, which has the same stimulus member but a different response member (Postman 1961; Underwood 1964). Although there is a great deal of evidence for this and related findings, it remains true at present that the mechanism by means of which such interference occurs has not been clearly delineated. The idea that there is "response competition" (Postman 1961) is a widely accepted view but seems little more than a renaming of the phenomenon of interference itself. A more promising possibility is the suggestion that the learning of a second response member also requires the complete erasure of the first from memory, that is, it extinguishes it after the fashion of extinction in a conditioned response (Barnes & Underwood 1959).

A quite different sort of hypothesis concerning the nature of negative transfer as it occurs in associative learning is receiving increasing attention. This is the proposition that the interference of a first task with a second (as in the arrangement A-B, then A-C) does not affect the learning of the second task at all but only its retention (Tulving 1964). This idea is consistent with the more general notion that the learning of each associate occurs in a single trial. Such a view, carried to its logical conclusion, would lead to the belief that negative transfer is essentially a process that reduces the probability of recall of learned associates in the phenomena called proactive interference and retroactive interference.

Transfer by means of concepts. The learning of relational concepts like "middle," "below," and "the odd one" and object concepts like "tree" and "door" has the effect of freeing performances from specific stimulus control. Having acquired a concept through learning, the individual is able to deal with a great variety of specific instances of the class that the concept represents. Particularly, it is true that the individual's performance can be correctly mediated by a concept, even though the specific instance to which he must respond has never been encountered during learning (cf. Kendler 1964; Gagné 1965). Concepts, therefore, are intimately bound with transfer of training. In order to demonstrate that an individual has learned

a concept, one must show that the effects of the learning will apply to not previously encountered members of the class of stimuli that are denoted by the concept's name. The mechanism by means of which the central nervous system accomplishes this feat of generalization is not well understood at present. This kind of capability is, of course, not restricted to human beings, although human conceptual behavior seems often to involve the use of language (Kendler 1964).

Transfer from principles. If principles are thought of as combinations of concepts, then for a similar reason they too provide the basis for transfer of training from the specific instances of learning to a large class of performances. The learning of a principle must be demonstrated by means of a test of transfer of training; it must be possible to show that the individual is able to apply the principle in a variety of situations that have not been specifically presented during learning (Gagné 1964). Hendrickson and Schroeder (1941) showed that the direct teaching of a principle in verbal form to high school students resulted in positive transfer to the task of hitting a target under water and that the transfer was greater than that produced by direct practice. Katona's findings (1940) concerning the transfer value of learning principles in the solution of card-trick and match-stick problems have been verified and elaborated by Hilgard and his colleagues (1953). To these laboratory studies concerning the effectiveness of principle learning for transfer must be added a great mass of unrecorded observations of teachers, who do not hesitate to assert that a principle such as is implied by the expression $a \cdot b + a \cdot c = a(b + c)$ accomplishes the job of knowledge transfer better than almost any number of specific examples like $2 \cdot 3 + 2 \cdot 4 = 2 \cdot 7$.

Transferability of learning

There are, then, a number of ways in which transfer can come about in behavior, ranging from the relatively specific stimulus generalization of a conditioned response to the very broad applicability of a principle. Whatever particular objective learning may have, it is reasonable to state that it will always be accompanied by an additional outcome of transfer of learning. So far as formal education is concerned, and even more broadly for the functioning of the human individual in society, the transferability of acquired knowledge and skill is often considered a more important goal than any number of specific learning accomplishments. For it is such transfer that makes it possible for the individual to solve new problems, to adjust to new

situations, and to make novel inventions. Enthusiasm for transferability as an educational goal needs to be tempered by the reflection that transfer depends upon prior learning.

X

ACQUISITION OF SKILL

In the scientific inquiry into the nature of skill, which has been largely conducted by experimental psychologists, operational definitions of skill are generally stated in terms of overt responses and controlled stimulation. Responses are subdivided into three types: verbal, motor, and perceptual, which typically stress speaking, moving, and judging, respectively. Common verbal tasks require the memorization of a list of words; motor tasks demand precise movements of the limbs and body; and perceptual tasks require discrimination of sensory information. Responses are evaluated or scored by means of errors, rates, pressures, amplitudes, time sharing, and information trans-

mitted. Stimuli, on the other hand, are energy inputs to the operator and are expressed in units, such as frequency, length, time, and weight.

The study of skill has largely been confined to a relatively few laboratory tasks and trainers. The inquiry has been directed far less to the arts, the shop, and the playing field than to identifying variables that cut across many jobs and finding general laws that stand for many specific tasks. For example, practice, rest, feedback, and transfer are prominent variables.

The work of the skills psychologist may be divided into two parts. In his basic research, he seeks relevant variables, discovers empirical laws of relations between variables, and constructs theories to account for the laws. In his applied work, he takes part in selecting personnel for special jobs, helps to design display and control stations, and prescribes some of the training rules of educational programs.

World War II provided the impetus for an accelerated study of motor skill. It was necessary to select from hundreds of thousands of men a limited number to fly airplanes, aim gunnery equipment, etc. A battery of tests to determine psychomotor abilities was developed containing eight apparatus tests: tracking moving targets, setting dials, etc. A candidate's performance rank on these devices turned out to be very much related to his proficiency during later training for aircrew stations in air force schools. The devices used in the apparatus tests did not resemble air force or civilian hardware, yet they brought out basic learning and performance factors, such as reaction time, speed of movement, and pattern discrimination common to operable equipment. The great success of the apparatus tests in predicting later behavior led to the accelerated growth of both theoretical and applied studies of skills. One of the specific accomplishments was to provide an impetus to the laboratory study of what skills are and of how they are learned.

Tasks involving continuous responses. The major components of a typical research device involving continuous responses include (1) a visual display station, such as an oscilloscope; (2) a mechanical or electronic means for programming the display, such as the movement of a pip of light in some prescribed way; (3) a station with a control, such as an airplane stick, for the operator to compensate for pip movement; and (4) a means of measuring the operator's response output with respect to the stimulus input. Appropriate stick responses for spatial coordinates x and y balance or neutralize the programmed displacements,

and the pip remains quiet, centered, and under control. Ordinarily, several groups of operators or subjects are trained, each group under a special condition. One set of conditions may involve change in the properties of the apparatus; another set may involve change in the methods of training. Obvious display variations are changes in target speed and path complexity; simple control variations involve resistance to movement and amount of pip movement per unit of stick displacement. These and other variations have led to the discovery of quantitative relationships between responses and the conditions of practice. In addition, all of these variations are often treated by a systems approach in which the output of men and machines is expressed as a function of the input. Examples of maturing areas of application are the piloting of aircraft and submarines and target detection and identification in radar.

The training expert gives advice on schedules of practice: when, how long, how often. He decides on practice matters pertaining to individual tasks: their relative emphases and staging. He makes important recommendations on the operator's data-processing abilities and need for training aids. The operator may be in for long periods of vigilance, and he ought to detect faint or occasional signals; in addition, the operator is expected to make suitable decisions in the available time and to select and execute the proper response for the system. The expert's most critical analyses center on feedback (information about past performance) and the manner of its representation, since any solution for coding the feedback (which is essential) necessitates selecting a sensory modality and temporal, spatial, and numerical schedules of transformation.

Tasks involving discrete responses. One major premise underlying tasks involving discrete responses is that the next response (R) depends upon the knowledge of results of previous responses (KR), that is, $R = f(KR)$. The relations between KR and R are arbitrary, and transformations always obtain. For example, if a blindfolded person were directed to "Draw a 3-inch line," he need not be informed of his error after each and every attempt, nor are we compelled to report a $+\frac{1}{2}$ inch error as "too far by $\frac{1}{2}$ inch." It is possible, of course, to report any numerical error at any time.

As the line-drawing example shows, targets and responses need not be in continuous motion, although the variables of continuous and discrete types of tasks are quite similar. The task of learning to move levers and knobs through a critical

distance has afforded a simple situation for studying the conditions regulating learning and performance. In these simple tasks, the simplest train of events is $R_1, KR_1, R_2, KR_2, \dots, R_n, KR_n$; the timing can be anything at all. A few illustrations of typical findings will suffice: (1) the massing of trials produces faster learning than does spacing; (2) the occasional omission of KR does not prejudice the effect of a later KR on the following R ; and (3) even day or week intervals between R and KR do not necessarily impair the learning of R . The learning of R , however, is seriously handicapped by (1) KR s which are vague ("You didn't do very well") and (2) KR s displaced from their normal position by another R , that is, R_1, R_2, KR_1, R_3 , etc. Some investigators interpret the primary role of KR as reinforcing in much the same way that food can be used to shape the behavior of the hungry animal. Others interpret the primary role of KR as informational and treat it as a stimulus variable that serves as a representational code for the response or its effect.

Work tasks. A man's output is dependent upon his recent and remote history of responding. His rate of work, for example, depends upon such obvious variables as work periods, rests, and loads. Rate also depends upon anticipated conditions of practice, rest, and load. According to the reactive inhibition theory of work decrement, decrement in performance is attributable to the build-up of reactive inhibition, and recovery in performance is attributable to the decay of inhibition. This theory is quite elaborate and effective; indeed, it explains a great deal more decrement data than do physiological-fatigue theories.

Among work tasks that have been studied are prolonged efforts at cranking, canceling letters of the alphabet, and packing small objects. The investigation of vigilance, a related topic, arose with the introduction of radar—watching radar is associated with infrequent, but critical, stimulation and with losses in performance at the critical moment. Losses in proficiency, however, may be caused by other means, a prominent one being response overload. Overload can be readily brought about by requiring reactions to more than one task. The breakdown in monitoring the incoming signals is intensified by increasing their number, complicating their constitution, or raising their frequency.

Forgetting. A learned series of skilled procedures, such as an instrument check-out sequence, is much more susceptible to forgetting than a response that requires muscular coordination. The forgetting of a motor skill that may occur over periods of extended disuse is quickly overcome by

comparatively few trials of retraining. Still, forgetting of even simple motor skills has been demonstrated, the phenomenon being more readily observed in changes in variance than in means.

Recent analyses of a person's ability to remember a list of words have shown that a person is far less likely to forget than experiments since the 1890s have led us to believe. Recent work on verbal retention has made more use of meaningful material—one word per subject and normative information on word-association structures—and more use of recalling under conditions of controlled retention environments. Retrieval of words from memory seems to depend strongly on free-association processes. Cultural norms have been tabulated which show the probability (p) of any response word to a stimulus word, for example, for the stimulus word *thirsty*, the $p(R_1)$ for *water* (the most frequent response) is .35, the $p(R_2)$ for *drink* (the second most frequent response) is .30, etc. If a naïve student is taught the word *drink* (as one of several words in a list), later, in the presence of the word *thirsty*, if *drink* is not recalled, *water* is likely to intrude instead. The illustration shows the effects of language habits established some time ago on present recall behavior (Bilodeau 1966a).

The explanations of forgetting are nearly all related to interference theory, either retroactive or proactive. If the reader cannot quite recall the items of yesterday's breakfast, it may be that this morning's fare intrudes or otherwise interferes (*retroaction*); if the failure to recall can be traced to breakfasts prior to yesterday, then *proactive* agents are to blame. The bulk of the literature favors retroaction as the mechanism of forgetting, but proactive is favored by present-day investigators.

Transfer of training. An individual is never tested or required to perform under the very same conditions which constituted training. There is always at least a small difference; sometimes there is a large one. The inquiry into the effects of these differences is called transfer of training. The objective of any training program is to maximize the amount of transfer, although examination of actual instructional programs might make us wonder. The student might be trained to read to himself, but when tested he might be required to read orally; another's training might be characterized by his watching, testing by his performing. Generally, it is found that learning almost anything (referred to as Task A) facilitates the learning of almost anything similar (Task B). That is, the transfer is ordinarily positive in sign. Generally, it is less than 100 per cent in quantity. In order to obtain more

than 100 per cent transfer, a training trial in Task A must be superior to a training trial in Task B when subsequently evaluated by the skill shown on Task B. Strictly speaking, more than 100 per cent transfer is most difficult to find. It appears that if Task B performance serves as the criterion, it is better to train at B and, if possible, avoid Task A from the start. Task B, however, in the hands of the novice may involve elements of danger or excessive expense, and so Task A may be substituted for Task B after all. For example, though it is probably true that the best training for helicopter piloting involves learning to fly the helicopter itself, the craft is dangerous and costly to operate. The ground trainers are inefficient, but if ten hours in them are actually worth five hours in the air, the 50 per cent transfer figure works to advantage.

The findings on negative transfer (detrimental effect of Task A upon the subsequent performance of Task B) are fairly clear. When Task A interferes with B, the interference is usually small and disappears quickly with additional practice on B. Indeed, there is even evidence to show that reversed forms of the same task involve the same psychomotor factors, and, further, there is no evidence for an individual trait of susceptibility to negative transfer. It can be speculated that to immunize oneself against negative transfer, or even to accelerate the normal processes of positive transfer, an exposure to any and many tasks is desirable. On the other hand, if a small amount of negative transfer includes one fatal error, the small amount should be considered most carefully.

Most psychologists believe that learning is an incremental process which could not take place without transfer. The number of constituent elements in two adjacent learning trials (A_1 and A_2) and the number of elements in common is believed to determine the amount of transfer. Because the events of training and education are never exactly reproduced in later life, a knowledge of the principles of transfer is of top priority for all users of applied skills research.

Composition rules. Skills have been analyzed and then synthesized by methods of probability, correlation, and geometry. A probability and a correlation model are sketched below to show how the reduction of skill to its components is accomplished in principle.

Probability model. Imagine that an operator views two meters whose pointers continually wander from center and that the pointers can be re-centered by means of cranks for the left and right

The stippled portions of the instances of B (that is, B', B'', B''') represent the temporal overlap of A and B, the time during which both hands are on target simultaneously. If A and B are fixed at probabilities of .5, time sharing is maximum (.5) for B', minimum (0) for B'', and at chance (.25) for B'''.

Figure 1 — An illustration of three levels of coordination between skills A and B

hands. Figure 1 represents a polygraph record of the on-off target time for hands A and B. The total time represented is unity and, for simplicity only, the probability (p) for each hand's being on-target is arbitrarily fixed at .5. Three special cases of coordination are shown: for A and B' the time that both hands are on the target at the same time is maximum (.5); for A and B'' it is minimum (0); and for A and B''' it is at the level of chance (.25). In each of these three cases, the hands are equally coordinated in the sense of equal proficiency at their separate tasks (.5); but in the sense of time sharing, the probability of the joint event $p(AB)$ ranges widely from 0 to .5. Somewhat surprisingly, many training situations yield results resembling B''' or chance time sharing, whatever the value of p . As a rule of thumb, the multiplicative formula $p(A) \times p(B)$ for independent events is used to produce a very good estimate of $p(AB)$. A better-than-chance score, then, is a show of positive coordination.

The multiplicative formula has a number of applications. If it is generalized to a three-part profile where, for example, $A = .90$, $B = .90$, and $C = .20$, the following predictions of their joint occurrence [$p(ABC)$] are possible: the best prediction is

$.90 \times .90 \times .20 = .16$; instant improvement may be dramatically obtained through any increase in the poorest part at the expense of a better part, $.70 \times .90 \times .40 = .25$; the maximum possible score is $[\frac{1}{3}(.90 + .90 + .20)]^3 = .30$; the worst possible score in a rearranged profile is .00. The training objective now becomes one of raising the value of $p(ABC)$. The most common way is to raise the sum of the part probabilities through additional standard practice. A second possibility is to make a change in the profile of the component parts, while holding their sum constant. Still a third method would strive to break the multiplicative rule and replace it with better-than-chance pairing of events.

The correlation model. Another method of skills analysis intercorrelates the scores from (1) within a single task but from different stages of practice and (2) different tasks at the same or different stages of practice. The two techniques reveal the amounts of variance (the statistic σ^2) common to two or more variables and establish the degree of relationship. The questions at issue involve abilities, pre-experimental experience, integration of components into total task, and training procedures. To date most of this work has involved the correlations among length of time scores, such as time on target in tracking tasks.

Intrataask analyses show relationships between (1) the first trial and successive later ones to be progressively lower and (2) adjacent trials to grow progressively larger. These patterns mean that the underlying composition of skill becomes simpler with increasing proficiency, for example, fewer abilities contribute to sophisticated than to naïve performance. Intertask analyses show that (1) predictor tests can provide better estimates for final than for initial criterion trials when the operator is skilled at both tasks; and (2) final level of criterion performance can be better predicted by extrataask measures than by earlier levels of skill on the criterion-learning task.

XI

LEARNING IN CHILDREN

Learning may be defined broadly to encompass relatively permanent behavior changes that result from experience. The experiential requirement usually implies that for the learning organism some changes in the associative properties of certain stimuli have taken place in such a way that the stimuli produce response effects that are different after training than before. Two general classes of empirical investigations in the area of children's learning may be cited. One type involves experimental manipulation of variables through laboratory investigation. Such studies have varied the number of conditioning trials, schedules of reinforcement, delay and magnitude of reinforcement, and motivational factors and have measured the resulting change in response or some attribute of response (Bijou & Baer 1960; Spiker 1960; Lipsitt 1963; White 1963; Rheingold & Stanley 1963; Munn 1946). The second category includes investigations of such training variables as familial or parental practices pertaining to feeding, toilet training, and effects of deprivation in infancy or in early childhood (McCandless 1961). The concepts of imprinting and trauma are not alien to this type of study, although little solid research with children is available on such matters.

Basic learning processes

Many of the experimental procedures used with animals and human adults have been adapted to the study of child behavior at all age levels. These studies generally indicate that for both classical (Pavlovian) conditioning and operant (Skinnerian) learning processes, the various pa-

rameters pertinent to conditioning in animals also control the occurrence and rate of conditioning in children.

Classical conditioning. It has been demonstrated that in classical conditioning in children, the time interval between the initially neutral stimulus (the conditioned stimulus, CS) and the initially effective response-producing stimulus (the unconditioned stimulus, UCS) is pertinent to the rapidity and strength of conditioning: there is an optimal interval of approximately half a second that varies somewhat with age and the nature of the response. A positive relationship has also been demonstrated between the drive or arousal level of the child and the rate of classical conditioning where that level has been variously defined by measures of muscular tension, tests of anxiety, or instruction-induced stress states. As in other organisms, it has been shown that the sensory modalities to which the CS and UCS are directed are pertinent to the conditioning process, as are the number of paired CS-UCS trials administered, and the nature of the tests used to measure the presence and strength of conditioning. In fact, the conclusion that conditioning has occurred often depends on the nature of these tests, including such procedural technicalities as whether interspersed test trials were administered among the training trials, whether conditioning was measured solely during extinction, or whether the response-recording apparatus permitted detection of subtle aspects of the reaction. In short, classical conditioning in the infant and child is a well-documented phenomenon, although knowledge of the variables affecting the phenomenon, including the age of the child, requires additional and extensive investigation. At present it appears quite likely, for instance, that there is an interaction between the age of the child and certain other parameters pertinent to the speed and strength of conditioning. One suggestion is that a younger child may require longer CS-UCS intervals for optimal conditioning than an older one.

Several investigators have recently established classical conditioning in neonates under rather well-controlled experimental conditions. Conditioning of appetitive responses is apparently obtained somewhat more easily than is classical conditioning of avoidance responses, at least under the levels of noxious stimulation that have been utilized. Some investigators have pointed out that fetal response to oral stimulation is developed neurophysiologically very early and that this response, and presumably its conditionability, has great survival value for the organism and the species. It can be

pointed out, however, that certain withdrawal reactions to aversive stimuli also develop early and, under adverse circumstances, could play an important role in the survival of the organism. Again, investigations involving both appetitive and aversive processes in infants are much needed.

It may be added that the behavioral phenomenon of habituation has been well documented in infants and children, just as it has been with a wide variety of infrahuman organisms. Habituation is a progressive diminution of response that occurs as a result of repetitive presentation of a given stimulus. There may be, in fact, several different response-decrement phenomena, resulting from different conditions of stimulus presentation and varying histories of the organism, only one or some of which might be properly classified as learning processes.

Operant conditioning. Operant conditioning has also received considerable attention from investigators of child behavior. The systematic reinforcement of a response initially low in the child's hierarchy of responses importantly affects the rate at which that response will subsequently occur. Operant conditioning may involve the presentation of a "positive" event contingent on the desired response. Examples of such positive reinforcers would be the awarding of candy or the introduction of a signal indicating correctness of response. Alternately, "negative" reinforcement involves termination of an aversive stimulus contingent on occurrence of a response to be learned. Both kinds of reinforcement ultimately yield increases in the response to which the reinforcement is addressed. A third type of response-contingent event is the withdrawal of a positive reinforcer on the occasion of an undesired response. Automatic obliteration of a motion picture, for instance, has been shown to be most effective in terminating or suppressing undesired behavior, such as thumb sucking in children. The operant technique capitalizes on the well-known law of effect and has been shown under many experimental arrangements to exert powerful control over various kinds of behavior, including imitative responses, smiling, emission of expressions of courtesy, and language. It has been found that different types of reinforcement schedules (e.g., intermittent versus continuous) tend to produce different response patterns in children; these patterns result in differential susceptibility to extinction when the reinforcer is ultimately withdrawn.

Discrimination learning. Discrimination learning studies are another type of conditioning investigation having to do with effects of reinforcement in maintaining or generating certain kinds of be-

havior. These studies typically involve discrete trial procedures rather than techniques that permit the subject to respond at any time. In discrimination learning, the child is rewarded for choosing the correct manipulandum, or correct stimulus, among multiple opportunities present. Numerous parameters have been shown to influence the occurrence and rate of children's discrimination learning, including some variables that are unique to the articulate organism and, therefore, affect learning differently at different ages and in children of varying intelligence and social circumstances. Such studies of children's discrimination learning have contributed importantly to the development and extension of behavior theory; this seems to be particularly true in the areas of verbal learning and mediational (cognitive) effects upon performance.

It has been demonstrated in children that presenting the discriminative stimuli simultaneously generally produces more rapid learning than presenting the same stimuli successively, particularly if the response required is directed at or involves the manipulation of those stimuli. However, successive presentation and simultaneous presentation do not produce very different effects if the response is to be made to a locus removed from the stimulus source, such as buttons that are some distance away from the stimuli. Although psychophysical scaling of discriminative stimuli would be required for a meaningful comparison of the ease of discrimination learning in one sense modality with another, it appears that learning is more easily achieved when the discriminative cues involve variations in stimulus size and less easily achieved when the stimuli vary in color. Solid (stereometric) objects tend to be discriminated more rapidly than do two-dimensional representations of the same figures. Greater magnitudes of reward (including more preferred rewards) and lesser delays of reward produce more rapid learning than their opposites; recent data, however, suggest that the relationship may not be a monotonic one and that greater delays may result in better retention. Studies are needed of interactions of such incentive attributes of rewards as size and delay with factors affecting drive or arousal level, such as frustration. In some circumstances, increased delay of reward, for instance, may lead to poorer performance; but in other circumstances it is possible that such delay could increase frustration, which may in turn facilitate some aspect of performance, particularly those responses that are already prepotent.

Much new research on children's discrimination learning has dealt with effects of variables that

have been historically of great interest to the general experimentalist but that only recently have been selected for extensive study by child psychologists. Some of these, for instance, pertain to the relative importance of positive and negative stimuli (i.e., reinforcement versus nonreinforcement) with most results indicating that both types of trial enhance performance.

Orientation behavior. White (1963) has noted that orientation behavior of children, or "observing responses," has been neglected by most experimenters, perhaps partly because this aspect of behavior is seldom included in formal learning theories. Because visual scanning of stimuli increases sharply at the onset of criterion performance in discrimination learning, an attentional shift important to the production of criterion or solution behavior is not unlikely. Studies of attentional behavior in discrimination learning as well as studies of observing behavior per se are becoming more frequent. In particular, a marked interest has recently arisen in the orientational behavior of human infants, wherein children from birth onward are provided with visual (and other) stimulation to which their reactions are recorded. It has been demonstrated that neonates respond differently to visual stimuli, depending primarily on the complexity of those stimuli, and that shifts in interest (defined in terms of length and frequency of fixation) occur with increasing age and experience. Since visual fixation occurs very early in life and is seemingly controlled by at least crudely specifiable stimulus attributes, there exists the intriguing possibility that attentional responses may be trained or conditioned very early through systematic reinforcement. Some writers, moreover, have suggested that visual orienting behavior of infants and the early changes in such behavior may be analogous to imprinting behavior found in lower organisms. Although much of this remains to be studied, the implication is that young human beings may "reach out" and follow with their eyes much as lower animals fixate upon and remain with objects that they encounter early [see ATTENTION; IMPRINTING].

Transfer of learning. Much work in children's discrimination learning has dealt with transfer of training. The phenomenon principally involved is that of generalization, whereby learning a certain response to a given stimulus predisposes the organism to respond to other similar stimuli, and proportionately so the greater the similarity.

Two general types of transfer of training, i.e., nonspecific and specific, have been extensively studied in children. Both of these are pertinent to the generalization of learning from one situation

to another, whether from one laboratory situation to another, from the laboratory to "real life," or from one "real life" situation to another. Nonspecific transfer, variously referred to as "warm-up" or "learning to learn" depending upon the conditions used to induce it, refers to the subject becoming "set" to perform in certain prescribed ways. This type of transfer has to do with the skills involved in manipulating the response objects, viewing the stimuli properly, or merely relaxing and awaiting instructions. Quite possibly, such warm-up may impair as well as facilitate subsequent performance depending upon the requirements of the subsequent task. Specific transfer may also either facilitate or impair performance, and it refers to the influence of earlier task requirements on subsequent task performance, particularly to whether the previously learned task is similar or not to the subsequently learned task.

Many studies of specific transfer in both verbal and motor discrimination learning have been done with children. Much of the paired associate work with children has concentrated on the negative transfer phenomenon, created by retraining the subject to make new responses to stimuli to which other responses had been previously learned. Many of these paired associate studies, however, have dealt with verbal mediation that can produce either positive or negative transfer depending on the specific stimuli and responses involved. Some of these studies of proactive facilitation or interference deal with the phenomena of acquired distinctiveness or acquired equivalence. Acquired equivalence studies have demonstrated that children have more difficulty learning differential responses to stimuli to which they have previously learned similar names, whereas acquired distinctiveness studies have shown that if children have previously learned different names for the discriminative stimuli any subsequent learning of differential responses to the stimuli will be easier.

Transposition and verbal mediation. Considerable attention has focused on a special kind of training transfer in children—that known as transposition behavior. Typically, the child is first trained to select one of two or more stimuli simultaneously presented, such as the larger of a pair of circles; transposition is said to have occurred if the child, when confronted with a transfer task involving presentation of the larger stimulus together with a still larger one, chooses the largest rather than the specific stimulus to which response has been previously reinforced. Lower animals often show transposition when the transfer pair is very similar to the training pair but a breakdown

in such transposition when the test pair is more dissimilar. Several studies have shown that the same is true for young children, but total transposition tends to occur with older or more articulate children. Presumably, possession of a concept, such as "larger than," accounts for extension of transposition to the very dissimilar stimuli. Transposition attracts developmental interest because transposition behavior clearly tends to change with increasing chronological and mental age and because language skill seems to bear an important relationship to the phenomenon.

Corroborative evidence for the importance of verballity in discrimination learning is found in studies comparing "reversal shift" with "nonreversal shift" procedures. The typical experiment involves the presentation of stimuli varying in two dimensions, with one of these dimensions providing the cues pertinent to making the correct response. For instance, both size and brightness might be varied, the child being required to respond to the dark rather than the bright stimulus, regardless of size. A reversal shift would involve a change to making a bright response correct, while a nonreversal shift would make size the pertinent dimension. Nonreversal shift has been found easier for animals and young children; reversal shift is easier for adults and more articulate (or older) children. Presumably, verbal mediational factors, such as the subject informing himself covertly of the pertinent dimension, are crucial [see CONCEPT FORMATION].

The study of children's cognitive processes has been approached recently by many students of paired associate learning and verbal mediation. While much exploration remains to be done on the mechanisms by which verbal or symbolic responses mediate and control behavior, it has become increasingly apparent that children are excellent subjects for such study. Work with children should enable extensions of behavior theory that would not be possible otherwise. There is the interesting and not unlikely possibility, moreover, that studies of verbal learning in children, including the phenomena of associative clustering, free association, and other aspects of verbal expression, will illuminate important personality processes and anomalies. The suggestion does not seem amiss, for instance, that self-concepts (the responses that humans make to themselves about themselves) may be viewed as covert verbal responses which are learned according to the principles by which other responses are learned and that these self-conceptualizations may act as mediational responses to affect subsequent learning.

Effects of early experience

The study of children's learning and the lasting effects of such learning necessarily includes any documentation of sequelae of "crucial" life circumstances. Thus, any studies relating parent-child variables or institutional factors as antecedents to behavior of children fall within the scope of the present topic. Effects of traumatic experiences and psychodynamic hypotheses about such effects ultimately refer to learned changes in behavior that reflect familial or other social circumstances. One of the difficulties inherent in the study of the relationship between such early experiences and later behavior is that the behavioral phenomena must occur *in natura* to be the subject of study, since it is impossible or undesirable to produce such behavior deliberately. Consequently, factors other than those specifically investigated have the opportunity of producing effects on the behavior studied. For instance, it has been demonstrated that infants who were rated as being permissively fed engaged in more "reality play" at preschool age, whereas children who were rated as being rigidly fed engaged in more fantasy. While such a finding is interesting and suggestive and does support clinically held presuppositions about the influences of feeding schedules on children's behavior, the possibility exists that both rigidity in feeding and the occurrence of fantasy behavior in children are products of a common type of parenthood. This possibility necessarily attenuates the cause-effect relationship one would wish to infer from the data.

The same methodological weakness lies in the cross-cultural approach to collecting developmental data on effects of early-experience factors. For instance, it has been shown that there is a rather high negative correlation between the age of weaning and intensity of guilt feelings among members of a large number of cultures. While it is tempting, on the basis of such data, to conclude that guilt is produced by early weaning or oral frustration, it is possible that those cultures which reinforce guilt responses are also those which happen to wean early. Perhaps both guilt and early weaning are behavioral phenomena produced by some third causative factor. Another study related oral pessimism and optimism to age of weaning (whether before or after four months of age), and found that the oral pessimists tended to have been weaned earlier. A number of studies exist that, like those cited, implicate the age and style of weaning as causatively pertinent social determinants of later behavior, but few of these studies permit more than conjectural conclusions.

Toilet training. Another area of children's social training which involves a great investment of parental time and produces considerable conflict and anxiety is toilet behavior. Just as certain crucial interactions between parent and child may occur around oral activities when the child is in infancy, so later may the child's excretory activities become the focus of much parental attention. Studies suggest that toilet-training practices do constitute an important "arena" within which parents and children interact, often unpleasantly, to produce potentially lasting developmental effects. The earlier toilet training starts, the longer it takes to complete. Also, the earlier such training starts, the more annoying, frustrating, and generally unpleasant experiences there are likely to be between the parties involved. Rigid toilet training, along with a constellation of other restrictive parental attributes, seems to be associated with slower development, and mothers who are high in anxiety tend to start toilet training earlier than more relaxed mothers.

Deprivation of social stimulation. While effects of institutionalization and, in general, deprivation of social stimulation remain to a certain extent controversial, the bulk of evidence suggests that such experiences often produce serious emotional and intellectual deficits. The effects are not as controversial as is the specification of the real antecedent events producing these effects, e.g., whether the pertinent variable is separation from a mother or sheer reduction in human or environmental contacts. It does seem reasonable to assume that institutional and deprivational effects consist largely of sequelae to previous unfortunate learning circumstances [see INFANCY, article on THE EFFECTS OF EARLY EXPERIENCE].

XII

PROGRAMMED LEARNING

The term "programmed learning" is used to describe an instructional situation in which materials presented in a controlled sequence require the learner to respond in a way that meets specified criteria of the program objectives. Terms often used synonymously are "programmed instruction," "automated instruction," "automatic tutoring," or even "teaching machines."

Because of the control over responses and sequence of presentation, the materials are referred to as a "program." The responses made by the learner may be completing a statement with a word or words, writing an answer to a question, making a selection in a multiple-choice situation, imitating auditory or visual stimuli with oral or motor responses, stating agreement or disagreement, or solving a problem. The program may be presented to the learner through a mechanical device, known as a teaching machine, or in a book, known as a programmed textbook. The materials are programmed so that a tutorial situation is approximated without the immediate presence of a human tutor.

Programmed learning is viewed as a technological advancement in education and training developed in order to meet the increasing complexities in nearly all areas of human learning endeavor. In education, these complexities include the numbers to be educated, the rapidly expanding body of knowledge to be taught, and the special cases within a population—e.g., the intellectually gifted, the retarded, the delinquent, and the illiterate. Problems in management development and training-retraining associated with automation are concerns in business and industry to which the techniques of programmed learning are applicable.

History

Sidney L. Pressey. A device that could administer and score tests automatically was exhibited

by Sidney L. Pressey in 1924. In a description of the uses of this device in his educational psychology classes at Ohio State University, Pressey also described the effectiveness of this machine for drill and recitation ([1926] 1960, pp. 35-41). The machine, which looked like a four-key typewriter, presented multiple-choice questions to the student. After the student had completed instruction through lectures and text reading, the machine was used to test his retention. The key corresponding to the student's choice for each item was pressed. If the student made the correct choice, the machine would present the next question; however, if the student chose incorrectly, the machine would not advance. The machine recorded the total number of key presses for the entire test. The immediate bringing into awareness of the correctness of a response provided more effective application of several of Thorndike's principles of learning than could the normal behaviors of the human teacher. Pressey observed that students who were tested by machine for weekly units of work showed higher achievement than students who took conventional tests.

Educators and trainers gave almost no consideration to the work done by Pressey and some of his students with the machine. After several years of effort modifying the device and applying it to several types of courses at different age levels, Pressey stopped working on the device and stated that education could not stay in a "crude handicraft stage" but would have to begin "quantity production methods" ([1932] 1960, pp. 47-51). He also predicted that new instruments and materials would be developed to facilitate research and sweeping advances in education and learning. Whether because of cultural inertia or other reasons, automated instructional devices failed to become established among educators and psychologists.

B. F. Skinner. More than twenty years later, in the 1950s, B. F. Skinner (1954, pp. 86-97) pointed out that education as a technology of learning did not approximate in its practice those principles observed and confirmed in learning research. Skinner stated that there were two principles of the learning process that had to be considered by those involved in teaching and training. The first, "contingencies of reinforcement," he described as a serious application of Thorndike's "law of effect" since it makes certain that desired responses appear in the student's behavior and that these responses are immediately reinforced. The second principle maintains that reinforcement should be arranged or "scheduled" so that the learner continues to make responses, i.e., so that the material keeps him interested. Responses that successfully

approximated the criteria of learned behavior should be emitted by the learners, and any other responses would be considered a faulty arrangement of the stimuli presented to the learners.

On the basis of these principles Skinner stated that anyone wishing to control the learning situation so that the desired changes in behavior would occur must consider the following questions: (1) What responses are desired to meet the criterion of learning? (2) What sort of successive approximations in emitted responses will lead to the desired behavior? (3) What reinforcers are available in the particular situation? (4) How can the reinforcements be arranged so that behavior can be maintained in necessary strength?

It was obvious to Skinner that educational practice would have to change radically to be able to construct an instructional situation that would meet these requirements. For example, almost no provision was made for each learner to emit successive approximations of the desired behavior, nor was there any provision for the desired responses to be frequently and immediately reinforced. He observed that the reinforcements used in education were usually indirectly related, at best, to the responses desired for learning and that the contingencies of reinforcement, if considered at all, are arranged most haphazardly. The teacher as the primary reinforcing agent certainly was not adequate in most instructional situations. Some sort of device was needed.

A number of studies followed in which programs and machines were developed and tested, applying the principles described by Skinner. Programs in the areas of physics, remedial reading and vocabulary building, spelling, German, arithmetic, algebra, and psychology were involved. Various machines were designed and built for these programs. Much of this work was done under Skinner's direction and influence and reported by him a few years later (Skinner 1958, pp. 969-977).

The mechanism, or machine, had a number of features differing from Pressey's. The learner was required to compose his answer rather than select one from alternatives. Skinner argued that in step-by-step approximations plausible alternative choices presented to the learner can potentially strengthen unwanted responses. The machine would present only one frame, or item, to which the learner responded, and all other frames were out of sight. The machine would not advance to the next frame until the learner responded correctly on the current frame. Coding the correct answers into the machine made this feature automatic. With older subjects it was felt that the learner could himself make the comparison between his response and the

correct one and that precoded answers might make the program too rigid. These frames were on a disc, which revolved on a turntable; the frames were exposed one at a time, and the learner composed his answer on a strip of paper exposed in another opening. After making his response, he raised a lever that caused his response to move under a transparent cover and at the same time exposed the correct answer. Lowering the lever caused the disc to expose the next frame. The machine could only control the presentation of the program. This control is most vital in the learning situation, but it is the program or material being exposed that teaches.

The characteristics of this learning situation can be described as follows: (1) The student is forced to be active in the learning situation. Unlike less-controlled situations, such as lectures, text reading, movies, or television, he is forced to make responses to stimuli as they are presented to him. (2) He must give the correct response before proceeding further. Again, this differs from techniques where the next stimulus can be presented whether or not the student is ready to proceed. (3) Through the step-by-step approximation, it is apparent when the learner is ready for the next step. (4) With hints, suggestions, and promptings the program helps the learner to make the correct response. (5) Immediate reinforcement is given to each appropriate response. The exposure of the answer is reinforcement, and this immediate feedback is sufficient to maintain the strength of the behavior, i.e., "keep him going."

Norman A. Crowder. Somewhat different approaches to automated instructional devices began to appear in 1958. These differed from Skinner's mainly in what was termed *intrinsic* programming: it was not so important that errors be completely omitted from the learner's responses but that the program should adjust to the correct or incorrect response. Examples of this type of programming are the Tab Item, digital computers that adjust problems automatically according to the learner's responses, and Crowder's automatic tutoring devices. Since Crowder and Skinner represent the two major approaches to automated instruction in the developmental period, the comparison will be made between what Crowder has described as *intrinsic* programming and what has been discussed concerning Skinner's approach.

Crowder's *intrinsic* program goes beyond "knowledge of results" to an evaluation of the communication process between the learner and the program. Crowder stated that it is impossible to understand the learning process with specific material so completely that perfect step-by-step approxi-

mation can be constructed. To overcome this handicap he built into the program an evaluation of the learner's responses in order to make corrections when the learner does not adequately understand each step. A simple example of how this is done is Crowder's "TutorText" (1960, pp. 286-298). A problem is introduced and the learner makes a choice among the answers that are presented at the bottom of the page in a multiple-choice arrangement. Along with each choice is a page number to which he is referred on the basis of that answer. If his answer is a correct one, he is informed of that fact and is presented with the next step. If his answer is incorrect, his error will be pointed out and explained, and he is referred to the original problem again. The "AutoTutor" is a more complex mechanism, which presents microfilm, motion picture film, or both and records responses and response time on a paper tape. Crowder described what he calls greater flexibility both within and between program steps. "Within-step flexibility" refers to each item of a page or screen presentation, and this is a larger amount of material than is presented in one frame on Skinner's program. Crowder states that this larger amount of material, or flexibility, is necessary because of the complexity of the material and the complexity of the learners. The "between-items flexibility," sometimes referred to as "branching," is necessary because all incorrect responses represent a communication failure that needs correcting, and this can be done only by repeating some items or introducing special items to clear the misunderstanding.

Another major difference between the approaches of Skinner and Crowder is the question of response mode. Skinner emphasizes the necessity of the subject constructing his response rather than responding to a multiple-choice situation. Related to this difference is the fact that the steps from one frame to the next represent a wide jump in Crowder's intrinsic programming as opposed to the small steps in Skinner's linear programming.

Programmed learning criteria

Regardless of the differences between what has been described as linear programming and intrinsic programming, certain criteria can be established for both, which distinguish programming from other techniques and devices of instruction.

(1) Stimuli to which the learner must respond are presented to him. Active participation is required of the learner in contrast to the situations of the lecture, textbook, and audio-visual aids.

(2) The sequence of the material presented is

highly controlled as a result of prior observation of its content within and between steps.

(3) A two-way communication is established, since immediate feedback is given by the program to the learner's response. The learner is aware of his progress at all times.

(4) Reinforcement or reward (usually this is immediate feedback) is used to keep the learner responding or interested.

(5) The learner responds to the program at his own rate; this then is similar to a tutorial situation.

(6) Learning occurs without a human instructor in the immediate situation.

Another way of contrasting the techniques of automated instruction with the more traditional educational methods is in the emphasis on what pays off for the learner rather than for the instructor. The lecturer, textbook writer, and the director of various audio-visual aids make use of those techniques which work for each in his own medium. In building a program the emphasis is on the learner's behavior at each step from beginning to end.

Research and development

The first reports of the use of programs in instruction began to appear in 1958, and most of the early reports were based on programs and machines developed and tested under Skinner's direction and influence. Much of this early effort was reported by Skinner in an article in *Science* which received a wide audience and gave impetus to the teaching-machine movement (Skinner 1958). In fact, the article was titled "Teaching Machines," and this was the first time these devices were given this label; the continued use of the term is an indication of the impact of that article.

Effectiveness of programmed instruction. The earliest research yielded some rather dramatic results that indicated a superiority of programmed instruction to more conventional techniques. This superiority was demonstrated in the significant differences found in the amount of time spent in learning and in learner performance.

The research and development in the next few years was phenomenal—a commentary on the value of this early effort and the tremendous need that many scholars felt existed for work in this direction. By 1964 more than two hundred research reports in programming appeared, directed toward the questions of whether programs do teach and, if so, which of the significant variables in the teaching-learning situation are under the control of the program.

The evidence leaves no doubt whether the pro-

grams teach: they do. Results of programs developed that use the models of Skinner, Crowder, or Pressey, as well as recent variations or combinations of these, contribute to this conclusion. Furthermore, learning occurs whether the program is presented by machine or in a text format. Learners varying in age from preschool to adult and in ability from the retarded and adult illiterate to advanced graduate student and practicing professional have been the subjects of these observations of program effectiveness. Programs have been used to teach motor, verbal, and perceptual skills at nearly every level of difficulty.

The question of whether programs teach more efficiently and effectively than other possible techniques was one of the first asked in research; in fact, most of the early research was concerned with a comparison of programmed instruction with conventional instruction. All but a few of these studies showed either a significant difference in favor of the program or no difference between the two. These observations were made with programs using the Skinnerian linear, or "shaping" model, the Crowder "intrinsic," or communication model, and the automated test model of Pressey. Although most of the programs constructed for these studies were of the linear type, enough programs employing the techniques of other models were used to indicate no inherent superiority of a particular set of techniques. It should be pointed out that these studies lacked the precision and thoroughness to warrant much confidence in them; the programs in most cases covered relatively small amounts of instructional material and generally were too crude and hastily developed to be exemplary of a desirable programming technology. Nevertheless, the results were such that most researchers felt that programs provided effective instruction, and because of the control over the teaching-learning situation inherent in the programming approach, their efforts were directed toward isolating those variables which make the instructional situation effective.

Analysis of the learning process. Most of the research has been done by psychologists and educational psychologists with the objective of basing a description of the learning process in instructional situations upon psychological principles of learning. Not since Thorndike had experimental psychologists interested in learning directed a concerted effort toward the application of learning principles in instruction. Because of techniques of behavioral analysis developed by Skinner and because of the respected position he enjoys among experimental psychologists, a great number of psy-

chologists were attracted to analysis of instruction through techniques of behavioral analysis developed in the laboratory. It was the application of the methodology to the applied situations in education and training, rather than a comparison of new and conventional instructional techniques, that attracted most psychologists. The major research, then, was concerned with isolating and describing the critical variables in the teaching-learning situation, using the method of behavioral analysis.

It was natural that many researchers began by attempting to replicate in modified form the earlier learning laboratory experiments and that the first of these were directed toward those variables found to be significant in Skinner's techniques of behavioral analysis. The techniques to be used for shaping the learner's responses, the effect of errors on this shaping process, the characteristics of the responses to be made by the learner, and the identification of the reinforcers in these learning situations were the problems covered in the early research; namely, how should the stimulus material be presented to the learner, in what mode and in what relationship to the stimulus should the learner's response be made, is confirmation of correct responses a reinforcement, and what effect does a high error rate have on learning?

Amount of information. A number of studies have focused upon varying the amount of information to which the learner is to respond. This amount ranged in scope from short statements to one or two paragraphs or even several pages of written material. The results of these studies are not easy to interpret; the amount of information is difficult to measure in terms of length alone and is not independent of the type of information transmitted. Generally the results favor smaller amounts, especially in the early steps of instruction. Since most of the studies used short programs involving a relatively small amount of information, critical tests of this question have yet to be made.

Sequence of information. Related to amount of information is the problem of how the information is to be sequenced. Should the information be arranged according to "expert" understanding of the specific material? Is there some logical pattern underlying the learning task that can be used in sequencing the material for instruction? Several experiments have failed to show any difference between ordered or random sequencing of the material, but these have been with short programs. A few studies that have been concerned with analyzing the material to identify categories of learning tasks for instructional sequencing appear as the major effort in attacking this area. By basing the

instruction on the learner's present repertory and then proceeding through the material that has been sequenced according to the characteristic responses to be learned, the studies have made a major contribution to the technology of programmed learning.

Mode and importance of response. A relatively large number of experiments have been concerned with the response mode, i.e., overt responses, covert responses, multiple-choice responses, or reading the same material with no required response. In the great majority of studies no difference has been found between the three types of active responses, and evidence does not clearly indicate that active responding is superior to merely reading the material. The results, however, do show a relationship between errors during learning and some criteria of performance at the end of instruction. When response errors are made in the program, evidence suggests that those students required to make a correct response before proceeding further, ultimately perform at a higher level. Obviously, a short program with a low error probability would not yield much difference, especially if the performance criteria were not particularly sensitive.

In addition to the mode of response, the question of the relationship of the response to the material has been investigated, i.e., is the response critical to the material presented by the stimulus? Although only a few studies have been directed toward this question, the evidence indicates superior results from those programs in which critical response is required.

The nature of reinforcement. The research area receiving the major emphasis in the early work in programmed learning has been the application of the principle of reinforcement. What is reinforcing in the programming situation? Confirmation of correct responses is not clearly a reinforcer in all programming situations; the responses of some students do extinguish in the presence of confirmation while those of others fail to extinguish in the absence of confirmation. In several studies the effects of prompting—the correct response being shown to the learner, who is then required to repeat it—have been compared to those of confirmation, and in most of these studies prompting led to higher performance than confirmation. Obviously, reinforcement in the programming situation is related to the incentive conditions under which the learner is responding. One study suggests that the appearance of the frame in the machine is itself reinforcing. Other efforts to control responses have made highly desirable behaviors contingent upon making responses in a program. For example, a peer-tutor situation makes use of this by requiring

the student to learn in order to teach another student. This has been most successful in teaching adult illiterates to read and write. Nevertheless, the complex relationship of intrinsic and extrinsic reinforcers present in human learning situations makes the task of identifying effective reinforcers extremely difficult indeed.

Errors. One of the clearest results of the research has been recognition of the relationship between the number of errors and performance criteria. Programs with a lower probability of response errors tend to be related to ultimately higher criterion performance. The cause of a high rate of error obviously cannot be separated from other variables in the instructional situation; therefore, attempts to solve this particular problem become somewhat circular. There has been no adequate analysis of the effect of errors in intrinsic programs except an awareness that a learner's attitude tends to be negative when the error rate is high. Regardless of the type of program, the evidence indicates that errors need to be corrected immediately before proceeding.

Evaluation. Since the beginning of concerted research effort to describe the significant variables in the area of programmed learning, one is struck by the high proportion of studies in which no differences have been observed. It is clear that the variables involved in effective instruction have not been isolated and described. Many studies that have registered observable differences are counterbalanced by contradictory evidence in other research or lack sufficient replication to allow extrapolation to general instruction procedure. While the effort has been considerable, the period during which this work has occurred has been a brief one, the programs have covered only small amounts of material, and the instruments for evaluation have lacked precision.

Potential

Although positive contributions to an instructional technology from specific research efforts are few, the fact remains that never has the teaching-learning situation received the attention of so many experimentalists interested in human learning. Programmed learning represents an application of behavioral analysis techniques to the learning of meaningful material. The controlled observations possible through programmed learning are making possible more precise descriptions of behavior in the instructional situation than at any time previously. The necessity of evaluating instruction with stated objectives in behavioral terms and the effectiveness of the principles of active response

and immediate reinforcement to instruction have been successfully demonstrated. From these beginnings a technology can be expected to develop which translates, in a systematic and highly generalizable way, the specified terminal behaviors into the form and sequence of the instructional task.

To many psychologists and educators the attraction of programming, and certainly the success of the approach thus far, has been the attention to laboratory research in learning. As noted earlier, however, the research in programming has been concerned with showing the influence of learning variables studied in the laboratory to applied learning situations; in general, the results of this research have been somewhat equivocal. Gagné (1962, pp. 85-86) has noted that the identification and arrangements of task components are more important in developing efficient and effective instructional situations than many of the variables studied in the learning laboratory, e.g., reinforcement, meaningfulness, distribution of practice, and so forth. Also, Melton (1959, pp. 100-101) has stated that laboratory research has not produced sufficient knowledge of different learning areas to allow an integration of possible generalizations to be highly useful in application. Melton also stated that there is yet no satisfactory taxonomical scheme to describe specific tasks that humans perform.

It is apparent that a number of factors are contributing to the absence of any rapid integration of a science of learning with an educational technology. The limited development of a science of learning, a taxonomy that allows placement of learning tasks in a dimensional matrix, the mutually exclusive efforts of the experimental and educational psychologists between the 1930s and late 1950s, and the complex interaction of variables in an educational learning situation are some of the obstacles that have held back such an integration. By the mid-1960s, however, these obstacles seemed to be disappearing. Experimental psychologists were introducing into the laboratory problems from applied instructional situations, and experimental and educational psychologists were cooperating on research projects at an increasing rate. Programmed learning introduced a methodology for observing and controlling behavior in an instructional situation which attracted the experimentalist, and the programming technique proved to be an effective instructional instrument which attracted the educational psychologist. Clearly the effort was made to build an educational technology from a science of learning just as an engineering technology was built from basic sciences. Equally clear was the necessity for an area of transitional

research to develop a taxonomy of tasks useful to technology and the science of learning.

Breadth of application. By 1965 there were more than a thousand programs published and available for purchase in the United States. Of these, approximately two-thirds were educational programs for courses or units within courses at all levels—elementary through graduate school. Programs were available for teaching beginning reading skills, mathematics at all levels, second-language reading and listening skills, spelling, grammar, punctuation, economic concepts, music fundamentals, statistics, genetics, biology, medicine, and physics. Many more programs were being developed or had been developed and were being used for limited objectives in specific classes. Programs were being used in other special situations, such as educational and vocational counseling, marriage counseling, interpersonal relationships, and the teaching of recreational skills.

Nearly three hundred programs in the field of business and industry were published and available by 1965; these included programs in areas of secretarial skills, management skills, bank teller skills, salesman training, and consumer training. Many more programs had been developed for the exclusive training of personnel of a particular company. Also, the military and the U.S. Public Health Service have developed a large number of programs to train their personnel.

Except in those cases in which the material presented or the response required demands a mechanical device, most programs are available in a text format. Language-listening skills, pitch discrimination, or the control of the responses of a small child are examples of such specific demands. The text format has provided economy and flexibility advantageous to programming's extended use in education, but the format probably has had a restraining effect on making broader application of the programming technique in education.

Use outside the United States. Because of the development of the programming technique in the United States, most research has taken place and the largest number of programs have been published there, but considerable effort in the research and development of programmed materials has been made in other countries. Considerable use of the techniques has been made in many European and Latin American countries, particularly in Great Britain, Germany, Sweden, the Soviet Union, the Netherlands, and Brazil. Much of the work has been done in these countries by following models of efforts in the United States. With the exception of the Soviet Union, a science of learning has not

developed in other countries to the extreme that it has in the United States, a fact which has limited the use of the programming model elsewhere. Because of a highly developed psychology of learning and its differences from that in the United States, the Russians might be expected to make significant contributions to the programming field.

In 1963, two UNESCO-sponsored workshops, one in Nigeria and the other in Jordan, introduced programmed instruction to areas of the world where it may have special significance. The necessity for more efficient and effective methods of education and training is especially great in the so-called developing countries, but this necessity is compounded by the world-wide scarcity of teachers. The self-instruction feature of programming makes its potential obvious.

There is little doubt that programmed learning represents a significant union of the science of learning with the practical problems of learning management. Effective teaching and training devices have been constructed. These early devices undoubtedly are extremely crude in comparison to what may appear in the future. The limit and potential of the use of programming in education and training are far from being determined in this early stage of development. The more important contribution of programmed learning to teaching and training is the introduction of a technique for an experimental analysis of behavior. Through the technique the practical problems of learning management can be brought under control so that careful observation and precise descriptions of learner responses to stimulus materials in an instructional situation can be made.

LEARNING THEORY

Since its emergence as a relatively distinct topic, learning theory has played a central role in psychology. Historically, many psychologists interested in the scientific understanding of behavior have worked with learning phenomena, while psychologists with major interests in areas other than learning, as well as workers in related disciplines, have considered learning to be a pervasive process that enters into quite diverse aspects of behavior. Widespread interest in learning theory has followed the recognition that the theoretical integration of facts and laws is an integral part of what is meant by scientific understanding and that theory serves useful organizational and conceptual functions. Objections to the theory aspect of learning theory have generally reflected disagreement concerning the schedule of the theorizing relative to the empirical development of the field, rather than questions of the ultimate desirability of theorizing about learning.

At the present time the kinds of activities subsumed under the rubric of learning theory present a rapidly changing and expanding pattern of interests. Because of this situation it is impossible to define or specify learning theory in any simple way. Indeed, neither "learning" nor "theory" is a term that is used with consistent meaning by those active in the area. Commonly, learning has been considered to be a process which results from practice and which is reflected as a more or less permanent change in behavior. In many traditional learning theories, learning has been carefully specified to be some sort of associationist process as distinguished from motivational, maturational, inhibitory, and fatigue processes. While learning is thus defined in some cases, even a cursory survey of those systems called learning theories reveals that they include motivational and inhibitory factors. In most such formulations, with the exception of mathematical theories of learning, consideration of motivational variables greatly overshadows concern with the more narrowly defined learning process itself. Thus, many learning theories are in reality theories of behavior, with the term "learning" more or less limiting the range of behavior included.

Similarly, the word "theory" is used in many ways, with an even greater range of meaning than is the case with "learning." At one extreme are theories which represent nonspecific verbal systems that better serve the "psychology of discovery" of the theorist than satisfy the basic requirement

of theories with respect to the integration of data or generation of testable predictions. In this respect, it should be noted that the present discussion applies the term "theory" to a wide variety of formulations, without requiring that they meet criteria of testability, usefulness, or scope. At the other extreme are very specific uses of the term deriving from its usage in mathematical logic. In more restricted uses of the term, there are theories which represent, in varying degrees of quantitative elaboration, hypotheses about the interrelationships of systems of constructs, such as those of the intervening variable type. Further complicating the picture is the increasing use of the term "model" (Lachman 1960), which has a similar variable meaning.

It is obvious that no simple classification of learning theory is possible, and instead of an attempt to develop an arbitrary classificatory scheme attention will be directed, first, toward the development of learning theory and, second, toward a characterization of present approaches and formulations.

The development of learning theory

In the United States, systems or theories specifically concerned with learning and motivation began to emerge in the late 1930s and early 1940s. Coming from a background of "schools" of psychology, for example, structuralism, functionalism, gestalt psychology, and behaviorism, learning theory took the form of systematic positions organized around individuals who promulgated systems of constructs, principles, and research strategies in attempts to account for varying ranges of learning phenomena. Closely connected with this development were the controversies which arose about the basic nature of learning and reinforcement. These controversies, which came to dominate much of the activity in learning at that time, furthered the establishment and growth of the individualistic systems.

Major systems. The major systematic positions were the subject of Hilgard's influential book *Theories of Learning* (1948), the book itself being instrumental in establishing the term "learning theory" in common usage. Among the systems described by Hilgard were Thorndike's early connectionism, Guthrie's emphasis on contiguous conditioning as a basic principle of learning, Hull's attempt to develop a highly rigorous quantitative theory based on data from simple learning situations, and Tolman's cognitive, gestalt-influenced theory, which stressed "sign-learning." The con-

tributions of Pavlov and Bekhterev certainly must be listed here also because of their tremendous influence on the development of learning theory and because of the importance of present-day neo-Pavlovian theory in the Soviet Union. [See the biographies of BEKHTEREV and PAVLOV.]

The learning theories of this period were characterized by Spence (1951) as being divided on two major issues: first, the nature of the concepts used to represent the hypothetical changes taking place in learning, and, second, the conditions believed to be necessary for these changes to take place.

Sign-significate versus stimulus-response. With respect to the first of these issues the comparison was between those (for example, Koffka, Köhler, Lewin, Tolman) who considered learning to reflect some kind of a perceptual reorganization or restructuring of the subject's cognitive field which corresponded to the stimulus relationships present in the environment; and those (for example, Guthrie, Thorndike, Hull) who conceived learning to be a modification of the strength of associations, habits, or response tendencies. The former were called S-S (sign-significate) theorists, the latter S-R (stimulus-response) theorists. The emphasis was directed, respectively, toward the effects of field conditions and other variables on perceptual organization and the relations between sensory events and toward the factors influencing the strength of associations, whether the associations were represented as empirical functional relationships or defined theoretical constructs. [See the biographies of GUTHRIE; HULL; LEWIN; THORNDIKE; TOLMAN; WATSON.]

Reinforcement versus contiguity. The second division was termed the reinforcement-contiguity issue. Here the distinctions concerned whether or not environmental aftereffects of behavior operated in some manner to change the strength of the learning process. Also involved were issues about the usefulness of special theories of reinforcement that attempted to identify the nature of the reinforcement or the manner in which the learning association was changed. Mention must also be made of two factor theories that generally postulated a classical-instrumental or autonomic-skeletal breakdown in which different kinds of learning were involved. These dual theories, which became increasingly popular, were held at various times by B. F. Skinner, Harold Schlosberg, O. H. Mowrer, and Kenneth Spence, among others. While many variations were proposed, contiguity principles were commonly paired with classical conditioning or with the conditioning of autonomic-

nervous-system responses, and reinforcement theory was usually paired with instrumental-skeletal responses.

Learning controversies. The learning theories and issues discussed above resulted in a great many disputes and controversies regarding the nature of learning, especially discrimination learning. Absolute and relational views of discrimination learning represented one such issue. The absolute position held that discrimination learning involves the strengthening or weakening of the response of approaching different aspects (discriminanda) of the total stimulus configuration, as a function of reinforcement and nonreinforcement; the relational position viewed discrimination learning as depending upon inherent perceptual-organizing tendencies, with the response always being to certain relational properties inherent in the stimulus configuration. This distinction also appeared in views of the nature of generalization and in analyses of transposition phenomena.

Another important controversy of the period centered on continuity and noncontinuity interpretations of discrimination learning, interpretations that were concerned with the question of whether an animal learns about environmental events which are being differentially reinforced but to which he is not responding differentially. The continuity position's answer to this question was, Yes; the noncontinuity answer, No. Interest in the problem declined because of the difficulty in testing the alternative positions that developed, although in a modified and less controversial form the general question of attention in discrimination learning remains an active area of interest. Finally, mention should be made of disputes regarding "latent learning," place (cognitive) versus response learning, and insight versus trial and error learning. [See LEARNING, article on DISCRIMINATION LEARNING; PERCEPTION, articles on PERCEPTUAL DEVELOPMENT and DEPTH PERCEPTION.]

The shift from major systems. It must be recognized that these positions and controversies occupied the major attention of learning theorists for a relatively long period during the growth of interest in learning phenomena and that much of the research of this time was in the context of these issues. Thus, the shift away from these formulations that began to be evident in the early 1950s marked a distinct change in both the direction and content of learning theory. This transition, which is clearly evident in a comparison of Hilgard's first (1948) and second (1956) editions of *Theories of Learning*, was due to a number of factors. Without detracting from the historical

importance of these approaches or the recognition of their essential contribution to all aspects of current learning theory, it can be recognized that the problems and limitations of the systematic and controversy-oriented theory of that period were such as to lead to change. As psychology became more sophisticated about applying testability criteria to theories, the demand increased that concepts and constructs (or the systems and models into which they were incorporated) should have empirical reference. It became obvious that many of the positions and controversies that had been the focal points of debate were not formulated in a way that would provide clear-cut empirical predictions. In other words, with some exceptions these were systems at the verbal level that could not be translated into the clear-cut experimental manipulations necessary for unambiguous testing. While adequately representing general approaches and serving certain heuristic functions, many of the systems did not serve a desired function of theories—that of integrating and predicting laws. It was also recognized that one possible reason for their lack of specificity was the range of behavior included. It was found that with the existing state of empirical knowledge, learning, as an area, was much too complex to be adequately handled by these broad approaches.

By and large the systems were concerned with simple learning situations; for example, classical conditioning, instrumental learning, and simple discrimination learning. While many learning psychologists recognized the strategy of building from the simple to the complex, they were not satisfied with the pace, were skeptical of the system-controversy aspect of the activity, or felt that important variables were being neglected. These workers, therefore, applied some of the techniques and concepts to other areas of interest or became involved in different kinds of theorizing. The changes as they have developed have represented a distinct turn toward "smaller" theories that are more closely tied to empirical data and that often deal with a single or closely related group of phenomena. Thus, these "smaller" theories have not been based on the theoretical predictions of a few dominant theorists, instead, they have proliferated as phenomena or areas of investigation have been developed or have caught the interest of investigators. Concurrently, there has come a great increase in the use of the model and in the utilization of mediation process notions in all areas of theory construction.

Current learning theory. Current activity in learning theory cannot be simply classified along

orthogonal dimensions, such as type of theorizing employed, type of learning phenomena involved, or experimental situations used. Rather than attempting to develop and justify a complex classificatory system, the following section will use broad categories that are intended only to serve a loose organizing function. Considered first are more general theories that have a relatively close relationship to the older systems; second, those which deal with classes of behavior or specific variables. In addition, theoretical activity concerned with traditional experimental learning situations, for example, classical conditioning, instrumental conditioning, discrimination learning, and verbal learning, is discussed, along with a brief consideration of more complex learning situations. It should be recognized that considerable overlap exists between these divisions and that many individual theories and areas of theoretical activity are omitted.

General approaches

While it is obvious that present-day learning theory is not primarily engaged in the elaboration of the theoretical structures of previous systems, the influence of older formulations is clearly represented in current work, and some theoretical activity has been rather directly derived from the "classical" positions. The latter has been the case more for S-R theory than for S-S approaches. There are several theoretical systems that are closely related to Hullian theory, and, similarly, the relationship of stimulus-sampling models to Guthrie's position is obvious. On the other hand, the influence of S-S theory is primarily evident in approaches that stress perceptual and cognitive variables, for example, perceptual models of discrimination learning and notions of cue utilization.

Modifications of S-R approaches. *Miller.* The changes in S-R approaches are exemplified by Miller's discussion of the "liberalization of S-R theory" (1959), which includes a consideration of the application of S-R concepts to central processes and the role of cybernetic-type feedback systems and attentional mechanisms in behavior. While admitting that postulation of central processes within an S-R framework reduces the difference between S-R and cognitive theory, Miller describes the S-R position as one that tends to apply the same laws to central processes as to peripheral stimuli and responses; this is in contrast to cognitive theory, which is characterized as being less specific about the laws involved. A characteristic of Miller's work has been his attempt to apply laboratory-developed theories and concepts to com-

plex social-behavior situations, the application of his theory of approach-avoidance conflict behavior to diverse and complex human behavioral situations being a case in point. In a sense this is a "model" approach, since the attempt is to find isomorphism between the systems developed in simple animal learning situations and complex human behavior. This approach is to be contrasted with that which attempts to expand theories dealing with a restricted range of simple phenomena by gradually integrating variables and laws from other behavioral situations. [See CONFLICT, article on PSYCHOLOGICAL ASPECTS; CYBERNETICS.]

Spence. Spence's theory (e.g., 1956) developed from early collaborative work with Hull. Starting with a quantitative S-R account of discrimination learning, Spence has developed in his later work a system that is more systematic than Hull's theory and much more closely tied to empirical data. In contrast to Hull's broader, less empirically based approach, is Spence's detailed concern with such topics as (1) the fractional anticipatory goal response, which is proposed as the mechanism underlying incentive; (2) the role of frustration in partial reinforcement and extinction; and (3) his theory of emotionally based drive. A major objective of Spence's theorizing has been to develop formulations that would allow for the derivation of empirical relationships found in a variety of learning situations and that could, with the addition of "composition rules," extend to more complex learning phenomena. [See DRIVES, article on PHYSIOLOGICAL DRIVES.]

Mowrer. Another theorist to be considered in this section is Mowrer. His most recent formulation (1960) assigns a central role to the classical conditioning of implicit responses or emotional states, which are called hope, disappointment, fear, or relief, depending upon the nature of the reinforcer (positive or negative) and the relation of the stimulus to the reinforcer (signaling its presence or imminent onset, or absence or approaching cessation). Mowrer is one theorist who does not follow the trend toward more restricted theorizing; rather, he proposes that his basic explanatory principles will encompass a wide range of human learning phenomena.

Mathematical theories. Perhaps the most rapidly expanding area of learning theorizing is that of mathematical (stochastic) theories of learning. Two principal lines of development have generally been distinguished. Statistical learning theory, or stimulus-sampling theory, has used conceptions of the environmental stimulus situation to obtain

learning axioms and theorems about the changes that occur in response probabilities as a consequence of environmental events. Operator models, on the other hand, have been primarily concerned with those properties of response sequences that are a result of various transformation rules; assumptions about outcome effects and response classes appear in the nature of the particular model. Both approaches share similar features, such as the assumptions that the environmental outcomes associated with response alternatives change the distribution of choice probabilities and that probabilistic mechanisms govern response selections. Mathematical representations of learning have been quite successful in handling the data from some learning situations. Often, however, these situations have been specifically arranged to lend themselves to mathematical treatment and do not represent paradigms commonly used by other theorists. Further problems have been the relative difficulty of deciding when a particular formulation is appropriate and the fact that there are often a number of alternative assumptions or models that lead to essentially the same results. While promising advances have been made, the future of this approach will be determined by its success in overcoming obstacles and arriving at transsituational mathematical representations of basic learning processes. [See MODELS, MATHEMATICAL; for a survey of this area, see Sternberg 1963.]

Phenomena-centered theories

Turning to theories which tend to deal more with certain kinds of behaviors or classes of variables, brief mention will be made of several areas in which the general shift toward phenomena-centered theorizing is evident.

Curiosity behaviors and reinforcement. One trend that has developed since the 1950s has been the increasing attention directed toward exploratory, manipulatory, and curiosity behaviors; and it is not surprising to find corresponding theoretical formulations which attempt to integrate the data of this area. One such theory is represented by the work of Berlyne (1960), who considers four variables to be of primary importance in stimulus-selection processes: novelty, uncertainty, degree of conflict, and complexity. The organism is presumed to direct attention both by central processes and by exploratory behavior (orienting responses, locomotor exploration, and investigatory responses) that alters the stimulus field. These variables are integrated with arousal-level concepts and further

tied to reinforcement, for example, in that arousal reduction may be reinforcing. [See ATTENTION; STIMULATION DRIVES.]

Concern with the nature of the reinforcing event is characteristic of formulations dealing with the effects of novelty, exploratory behavior, curiosity, and similar stimulus variables and response patterns. To a large extent this concern has represented dissatisfaction with the tendency of older theories to expand their motivational and reinforcement notions from a single drive or drive mechanism and with their disposition to concentrate upon a few biogenic drives, for example, hunger. Also contributing to this interest has been the demonstration of the high reinforcing value of visual and manipulatory exploration. This work, in which Harlow has played a major role, has forced learning to attend to a new class of variables in a manner similar to the way in which gestalt psychology focused attention on a previously ignored set of perceptual phenomena. While theory concerned with novelty, curiosity, and similar variables has generally not reached the degree of specificity associated with some other areas of theorizing, it is an active and promising area that will undoubtedly become integrated with theories that presently do not deal with these variables to any great extent.

A similar situation exists with respect to investigations of the orienting reflex. Starting with Pavlov's original work, the orienting reflex has proved a rich topic for research in the Soviet Union and has been the focus of a great increase of interest in the United States. The orienting reflex, which is considered to be a functional, centrally organized and integrated system of somatic, visceral, and cognitive reactions, is evoked by changes in stimulation or "novel" stimuli. Sokolov, the most prominent worker in this field, has elaborated a neuronal model concerned with the properties of the orienting reflex (1960).

Verbal processes. Of similar interest is the concern with the role of verbal processes in learning. While these processes play a major role in some theories of discrimination learning, interest in verbal processes also serves as a more general framework within which many theoretical formulations are being made. Work in the Soviet Union is particularly noteworthy in this respect. Coming from the separate but related traditions of Pavlov and L. S. Vigotski, Soviet researchers have increasingly been concerned with the second (verbal) signaling system and its relationship to learning. Luria (1961) among others has been quite active

in theorizing about the verbal regulation of behavior, especially voluntary movements, with an emphasis on developmental factors both in normal and abnormal children. Note should also be made of the growing interest in relating conceptions of orienting reflex and feedback to theories of the development of voluntary action. [See CONCEPT FORMATION; LEARNING, *article on* VERBAL LEARNING.]

Punishment. Another area that has seen a large increase in theoretical activity is that concerned with the effects of punishment on behavior. It has become clear that punishment can have a wide variety of facilitatory, inhibitory, or suppressive effects depending upon the behavioral, situational, and punishment parameters involved, and a number of theorists have attempted to integrate these effects into existing theoretical structures or to develop principles which will link the various experimental findings. Thus, some theorists have discussed the conditioning of anticipatory punishment cues or have considered punishment to be a special case of avoidance learning, while others have emphasized the role of fear, the nature of the skeletal responses elicited by the punishment, or the stimulus properties of punishment. [See LEARNING, *article on* AVOIDANCE LEARNING.]

Developmental psychology. Another increasingly active area with import for learning theory is developmental psychology. The recent trend in this area has been a de-emphasis of normative, naturalistic observation and an increasing use of the experimental method. Correspondingly, there has been a turning away from the "grand" developmental theories as theories, although their utilization as a source of ideas continues. Thus, the conceptual framework and insightful observations of Piaget have occasioned intense interest in developmental psychology, and considerable effort is underway to translate the system and specific ideas into experimentally testable form. As this sort of experimental activity continues, developmental psychology seems destined to have closer ties to other areas of psychology. Indeed, those working in various content areas have also been moving toward developmental concepts. It appears obvious that learning theory must utilize, include, or become integrated with specific experimentally based developmental theory if it hopes to make significant progress in the future. [See DEVELOPMENTAL PSYCHOLOGY.]

Neurophysiology. Brief mention should also be made of the current work on the neurophysiological basis of learning. Although learning theory of

the past has not emphasized physiological constructs to any great extent, this situation may well change as progress is made in understanding the neural basis of learning. It should also be noted that physiological theorizing has generally taken the form of hypotheses about the nature of the physiological or biochemical mechanisms involved. This is in contrast to learning theory in the United States, which has been much more inclined toward the use of systems involving defined concepts or constructs. Theorizing in both areas has felt the impact of the "model" approach, and some rapprochement may occur because of this. Learning theory in the Soviet Union has been much more closely tied to neurophysiological concepts. [See *LEARNING, article on NEUROPHYSIOLOGICAL ASPECTS; NERVOUS SYSTEM.*]

Other phenomena. Examples of theorizing can also be seen with learning phenomena of more limited scope. Thus, the effects of partial reinforcement in acquisition and extinction have served to trigger the development of "small" theoretical formulations that attempt to isolate the effective parameters in the experimental situation and to derive the effects from more basic learning phenomena, for example, stimulus generalization, or as special cases of more general learning theories. In some cases, empirical findings that have countered common sense expectations or the simple derivations of theory have served as the focal points of theoretical activity.

In these examples the phenomena-centered nature of current learning theory is evident, in contrast to the older formulations which tended to start with general principles or postulates concerning the nature of the learning or reinforcement process.

Current work in traditional areas

Classical conditioning. Contemporary theories concerned with classical conditioning have been summarized by Grings (1963). With some exceptions, for example, Razran's detailed schema, the primary theoretical work has been directed more toward various aspects of the conditioning process than toward the development of a general explanatory system of classical conditioning per se. Much of the interest in classical conditioning has been in its postulated role in other, presumably more complicated, kinds of behavior; for example, theorizing regarding incentive variables, such as the fractional anticipatory goal response, has made use of classical conditioning processes, or as Lachman (1960) discusses it, classical conditioning provides the model, that is, the inference rules,

for fractional anticipatory goal response theory. Similar theorizing has developed with respect to (1) the consequences of frustration, with frustration being defined either as the blocking of an ongoing response or as the omission of a reward, as in partial reinforcement or extinction; and (2) behavioral situations involving the use of punishment. Thus, in many situations where events are conceptualized to mediate overt behavior, classical conditioning is postulated to play some role or to serve as an inference model for the mediation theory. It should be noted that this use of conditioning is in the S-R rather than the cognitive tradition. [See *DRIVES, article on PHYSIOLOGICAL DRIVES; LEARNING, article on CLASSICAL CONDITIONING.*]

Soviet work. In the Soviet Union, theorizing about classical conditioning has remained a major interest since the pioneering work of Pavlov (e.g., see Anokhin 1955). The characteristics of Pavlov's theorizing are well known, and while many of his specific notions regarding physiological structure and function have been abandoned or modified considerably, present-day learning theory in the Soviet Union retains a physiological orientation. The current Soviet emphasis on interoceptive conditioning, semantic conditioning, and the orienting reflex is reviewed in detail by Razran (1961). Especially noteworthy, in the present context, has been the theoretical development coming from Soviet interests in configural conditioning, the role of conditioning in verbal behavior, and the ontogenetic implications of their work.

Instrumental conditioning. Theorizing involving instrumental conditioning has taken several forms. The effects of various parameters upon instrumental learning have been of interest to theorists who have attempted to integrate empirical relationships into a more comprehensive theory, or who have tried to use the laws obtained in these simple situations to develop formulations which would make it possible to derive the data previously obtained from more complicated selective-learning paradigms. The relative simplicity of instrumental conditioning has been attractive to those who have found the more complicated situations difficult to analyze in a precise manner. Phenomena-centered theorizing is quite evident here, as in other behavioral situations. To mention only two such efforts: certain partial reinforcement effects in acquisition and extinction have been of theoretical interest, and Abram Amsel's analysis (1962) of frustrative nonreward effects has been based on data from instrumental conditioning. [See *LEARNING, article on INSTRUMENTAL LEARNING.*]

Avoidance learning. Perhaps the greatest amount of theorizing concerning instrumental behavior has taken place with respect to avoidance learning. These theoretical formulations have generally been concerned with the mediating role of anxiety or fear in avoidance behavior and with the reinforcement principles operating in the dual learning processes of (1) fear or anxiety and (2) the instrumental skeletal response. A comprehensive overview of this area is presented by Solomon and Brush (1956). More recent theorizing has been concerned with specific avoidance phenomena, again demonstrating the trend toward more molecular theorizing. [See LEARNING, article on AVOIDANCE LEARNING.]

Selective learning. The original work in selective (discrimination) learning was largely concerned with controversies regarding the nature of learning and reinforcement processes. While some of this type of work is still found, current interest has largely shifted to the various processes—attentional, verbal, etc.—which presumably mediate the learning. A closely related development has been the emphasis on phylogenetic and ontogenetic considerations, in terms of discrimination-learning performance and the relative use of the postulated mediational mechanisms. One of the most important developments in the discrimination-learning area has been the learning-set work of Harlow (1959). This research focused attention on discrimination procedures, demonstrated the relevance of this sort of research for more complex learning (for example, concept formation), and provided behavioral techniques that have proved useful in comparing human and infrahuman learning. Theoretical activity has been concerned with the nature of interfering tendencies or error factors.

A great deal of current activity is concerned with discrimination-learning "transfer" situations. A number of paradigms have been used to (1) compare the learning processes in human and infrahuman organisms, (2) explicate the nature of postulated mediating mechanisms, and (3) examine the mediational processes ontogenetically. Theoretical approaches that should be mentioned here include those of Luria (1961) and Kendler and Kendler (1962), both of which have tended to identify mediational processes with verbal behavior, and that of Zeaman and House (1963), which has developed from work with retarded children and which, although mathematical in nature, emphasizes the importance of attentional responses to stimulus dimensions. These formulations demonstrate several trends in discrimination-

learning theory. First, the use of multistage mediational models to account for the data; second, the increasing use of normal and retarded children as subjects; and third, as in the case of Zeaman and House, the emphasis on observing or attentional responses. Other theories proposed for selective learning include the observing-response formulation of Wyckoff (1952) and the analyzer-mechanism approach of N. S. Sutherland (1959). A succinct phrase which describes the basic process of concern in a number of these formulations is "selective attention," which can be conceived of in terms of stimulus-response relationships and laws or perceptual-cognitive processes. Approaches which attempt the integration of verbal-behavior relationships with discrimination-learning processes are also popular.

Verbal learning. An excellent discussion of the nature of theory in verbal learning is available in a paper by Gough and Jenkins (1963). These authors point out that verbal learning—the "rote" learning of material under laboratory conditions—did not develop from the learning theories of the 1940s but from the work of Ebbinghaus and the functionalist school of psychology. As an area, verbal learning has always been very closely tied to empirical data and methodological considerations, with little in the way of broad systematic theory. The theories that have developed have been concerned with specific verbal learning or retention phenomena and, as Gough and Jenkins point out, often have been called "analyses" rather than "theories." This lack of broad systematic formulations has led to the development of "small" testable theories, which have been quickly modified to reflect new experimental evidence. A listing of some recent theoretical formulations or analyses gives the flavor of the work. It has been proposed by Underwood and Schulz (1960) that paired-associate verbal learning can best be considered as a two-stage process involving response learning and stimulus-response associative stages. A considerable amount of research has demonstrated the usefulness of this conceptualization. Underwood (1957) has demonstrated that the role of proactive interference in laboratory learning is much greater than was previously assumed, an advance that has contributed to the understanding of forgetting and has led to important changes in methodology. Finally, the development of the interference theory of retroactive inhibition has witnessed the introduction of the concepts of differentiation or the discrimination of list membership and unlearning or extinction to account for discrepancies between interference theory and the obtained data. The

close interplay between data and theory is apparent. [See FORGETTING; LEARNING, article on VERBAL LEARNING.]

Complex learning situations. Concept learning, skill learning, and problem solving are areas that have generally been considered to be more complex and harder to handle in terms of theory than those previously discussed. There are several dimensions of this complexity, for example, the ease or difficulty of dealing with discrete units of behavior or a limited number of basic processes and the necessity of considering sequential relationships. Until relatively recently, theorists were reluctant to deal with these situations, as demonstrated by the early discarding of problem-box situations for the simpler classical-conditioning and instrumental-learning procedures. The resurgence of interest in and of theorizing about these more complex areas has led to attempts to extend S-R and cognitive approaches to these phenomena, and, in some cases, it has led to new conceptual frameworks which bear little obvious relationship to traditional learning approaches.

Concept learning. Concept learning has, perhaps, remained closer to conventional learning research than the other areas mentioned. Kendler (1964) has pointed out that various learning models have been applied to concept learning. He lists S-R conceptions, operant conditioning, clustering, Piaget's methods of investigation, computer simulation of cognitive processes, and mathematical models as methods and models for the analysis of concept learning. [See CONCEPT FORMATION.]

Skill learning. In comparison to concept learning, theoretical activity regarding skill learning has been more removed from traditional learning theorizing. While issues such as the relative role of specific associations or cognitive sets in skill learning seem closely related to learning theory, the conceptual framework is not. Thus, the language of many models of skill learning is couched in terms of communication models, involving (1) notions of information processing, with subcategories of information translation, transmission, reduction, collation, and storage; (2) control-system models emphasizing feedback systems; and (3) adaptive-system models, with programs and memory systems which allow changes in the characteristics of the model with experience. [See LEARNING, article on ACQUISITION OF SKILL; see also Fitts 1964.]

Problem solving. Problem solving has long represented an area of controversy with S-R oriented theorists opposing gestalt-cognitive ap-

proaches. The S-R approach attempts to use such concepts as mediated generalization, response hierarchies, verbal mediators, and fractional anticipatory goal responses to account for problem-solving phenomena. Gestalt theory, on the other hand, emphasizes perceptual reorganization processes within the problem. One recent formulation or suggested framework, more in the gestalt than in the S-R tradition, has been the ahistorical, relatively rationally derived notions of Miller, Galanter, and Pribram (1960), which involve informational and feedback processes. [See PROBLEM SOLVING.]

The question as to what extent new language and methodological approaches are needed for theorizing in these complex areas remains to be determined. It seems evident, however, that information processing and feedback concepts of some sort will greatly influence learning theorizing in the future.

LEGAL REASONING

In countries like the United States and England, where thought about law has focused primarily on adjudication, legal reasoning is often identified with the intellectual processes by which judges reach conclusions in deciding cases. In countries like France and Germany, on the other hand, where thought about law has focused primarily on codification—that is, the creation of a complex and harmonious body of legal rules and concepts—legal reasoning is often identified with the intellectual processes by which the rationality and consistency of legal doctrines are maintained and justified. Since, as we shall see, both these types of reasoning are closely related to each other, we would define legal reasoning broadly enough to include them both; and indeed, we propose to broaden the definition still further to include also the types of reasoning used in other kinds of legal activity, such as making laws, administering laws, the trial (and not merely the decision) of cases in court, the drafting of legal documents, and the negotiation of legal transactions.

When legal reasoning is conceived of in these broader terms, it is seen to involve not only, and not primarily, the application of rules of formal logic but also other methods of exposition. To reason, according to dictionary definitions, may mean to give grounds (reasons) for one's statements, to argue persuasively, or to engage in discourse. Law, insofar as it has a distinctive subject matter and is founded on distinctive principles and purposes, has not only its own kinds of logic but also its own kinds of rhetoric and its own kinds of discourse, which are, of course, similar to the logic, rhetoric, and discourse of other social institutions and other scholarly disciplines but which nevertheless have certain distinctive characteristics.

In seeking to identify these distinctive characteristics, we must keep in mind that legal reasoning is not identical in all societies and that, in

addition, the degree of its distinctiveness is not identical in all societies. In a theocracy, for example, legal reasoning may be closely related to sacerdotal reasoning; at one time the high priests of Israel found the law by consulting the breastplates which they wore (the Urim and Thummim)—that is, their legal decisions were justified in terms of divine revelation. In a society that is undergoing a political revolution, such as the Soviet Union in the first years after 1917, legal reasoning may dissolve into the reasoning of politics and class struggle. These variations strongly suggest that in any society there is an intimate connection between the logic, rhetoric, and discourse of law and the dominant beliefs of the society concerning religion, politics, and other aspects of social life, including its beliefs about the nature of reasoning itself. Legal reasoning seems to be most distinctive in those societies that have experienced the emergence of a special professional class of lawmen, with its own special professional traditions and institutional values; here special modes of logic, rhetoric, and discourse seem to have as part of their functions the preservation and further development of the legal profession's traditions and values, although at the same time even in such societies the intimate connections between legal reasoning and other types of reasoning must be maintained if the legal profession is to retain the respect of the community as a whole.

Legal logic. Many Western jurists of the eighteenth and nineteenth centuries sought to make legal reasoning conform to syllogistic logic. The rules of law declared by legislatures, courts, and legal scholars were viewed as major premises, and the fact situations of particular cases or the terms of particular legal problems were viewed as minor premises. The decision of a case, or the resolution of a legal problem, was thought to follow inevitably from a proper juxtaposition of the major and minor premises. Given a rule or doctrine defining burglary, or contract, or any other basis of legal duty, it was thought only to be necessary to determine whether or not a particular act fell within the definition in order to determine whether or not legal responsibility should attach to it. It was supposed by many that if the entire body of law could be summarized in a set of rules, the sole remaining task of law would be to classify particular facts under one rule or another.

This mechanical model of the application of rules to facts did not go unchallenged even in its heyday. In Germany, Rudolf von Jhering ridiculed a "jurisprudence of concepts" (*Begriffsjurisprudenz*) and called for a conscious legal policy of

evaluating the social and personal interests involved in the legal resolution of conflicts (*Interessenjurisprudenz*). Similarly, in the United States, Oliver Wendell Holmes, Jr., in some of his writings, viewed the logical form in which judges announced their conclusions as a veil covering their views of public policy. The life of the law has not been logic; it has been experience, Holmes stated in 1881. By "logic" Holmes indicated he meant "the syllogism" and "the axioms and corollaries of a book of mathematics"; by "experience" he meant "considerations of what is socially expedient."

However useful syllogistic logic may be in testing the validity of conclusions drawn from given premises, it is inadequate as a method of reasoning in a practical science such as law, where the premises are not given but must be created. Legal rules, viewed as major premises, are always subject to qualification in the light of particular circumstances; it is a rule of English and American law, for example, that a person who intentionally strikes another is civilly liable for battery, but such a rule is subject, in legal practice, to infinite modification in the light of possible defense (for example, self-defense, defense of property, parental privilege, immunity from suit, lack of jurisdiction, insufficiency of evidence, etc.). In addition, life continually presents new situations to which no existing rule is applicable; we simply do not know the legal limits of freedom of speech, for example, since the social context in which words are spoken is continually changing. Thus legal rules are continually being made and remade.

Also the "minor premises"—the facts of particular cases or the terms of particular legal problems—are not simply "there" but must be perceived and characterized, and this, too, requires interpretation and evaluation. Indeed, the legal facts of a case are not raw data but rather those facts that have been selected and classified in terms of legal categories.

Finally, the conclusion, that is, the application of the rule to the particular case or problem, since it is a responsible decision directly affecting particular people in particular situations, is never mathematically inevitable but always contingent upon the exercise of judgment. In the telling words of Immanuel Kant, "there is no rule for applying a rule"; that is, there are no rules that can tell us in advance, with certainty, how a particular judge (legislator, administrator, etc.) ought to resolve a concrete case or problem that is before him—and this would be true even though we were able to say in advance what rules are relevant to such a resolution. Once a legal conclusion is reached,

it may often be stated in syllogistic form; but in the process of reaching it, the determination of the major and minor premises may have come last.

To say that legal reasoning cannot be reduced to the classical rules of formal logic is not, however, to deny that it has logical qualities. It is characteristic of legal reasoning that it strives toward consistency both of legal rules and of legal judgments; such a striving for consistency is implicit in the belief that law should apply equally to all who are subject to it and that like cases should be decided in a like manner. Even the judgments of the ancient Greek oracles were believed to reflect a hidden consistency. It is also characteristic of legal reasoning that it strives toward continuity in time; it looks to the authority of the past, embodied in previously declared rules and decisions, and it attempts to regulate social relations in such a way as to preserve stability. Finally, legal reasoning is dialectical reasoning; it is characteristically concerned with the weighing of opposing claims, whether expressed in legislative debate, in forensic argument, or the like. These three basic characteristics of legal reasoning impose upon it certain logical requirements.

The most pervasive form of legal logic is that of *analogy*, in the broad sense of the comparison and contrast of similar and dissimilar examples. Analogical reasoning is implicit in the striving for consistency; the striving for continuity (that is, historical consistency) also involves analogical reasoning, the analogies being found in past experience; similarly, the dialectical quality of legal reasoning involves comparison and contrast between the examples put forward by the opposing sides. (It should be noted that the term "analogy" also has a technical legal meaning, signifying the extension of a legal category to a situation which is "similar to" but not "the same as" those situations which the category "logically" includes; in contrast, we use the term "analogy" here more broadly and include under it the process by which it is determined that one situation is "the same as" another.)

In a legal system such as that of England or the United States, which stresses the authority of past judicial decisions (precedents), analogical reasoning in adjudication characteristically takes the form of (a) comparison of the fact situation before the court with the fact situations of previously decided cases in order to find a previously decided case whose fact situation is comparable; (b) extraction from the previously decided comparable case of the principle upon which that case was decided; and (c) application of that principle to

the case at hand. It is generally recognized that each of these three steps is dependent upon the other two. Moreover, the second step—the extraction of the principle of the previous case—is complicated by the fact that the principle expressly relied on by the court in deciding the previous case is not necessarily binding upon future courts. Even under a strict doctrine of precedents, at least as understood in the United States, a court, although bound by the decisions in previous cases, may reject the reasons previously given for those decisions—as, for example, where much broader reasons were given than were required. In technical terms, the court is not bound by (may treat as mere *dictum*) any statement made in a previous comparable case which was not necessary to the decision in that case; and even a reason stated by the previous court as the necessary ground for its decision may be treated as *dictum*, and not binding, if the later court considers that the same decision could have been reached on other (better) grounds. Thus what is binding on future courts—the "holding" of the case—is determined in part by its subsequent application to similar fact situations.

Reasoning by *analogy of precedents* has been called by one writer "the basic pattern of legal reasoning." However, another characteristic method of legal reasoning—especially (but not exclusively) in legal systems that do not recognize the binding force of precedents—is to decide cases or resolve particular legal problems by *analogy of doctrines* expressed in statutes and in other forms of legal rules. To give an American example: in the latter part of the nineteenth century, most states enacted statutes giving married women the right to own their separate property, to make contracts, and to sue and be sued. Using the authority of such married women's acts, many courts overruled various earlier precedents which made a wife and husband incompetent to testify for or against each other, which made a husband liable for his wife's torts, which made one spouse not liable to conviction for stealing from the other, etc. These matters, although not dealt with specifically by the married women's acts, were sufficiently similar to the matters with which the married women's acts did deal that the policy of those acts was considered to be applicable. Such use of analogy of statute (or of legal doctrine) is especially prevalent in those countries of Europe in which the law is largely found in codes and in which the writings of leading legal scholars in interpreting the codes have more authority than judicial decisions.

Analogical reasoning, and especially reasoning

from analogy of decided cases, is sometimes said to be "inductive," as contrasted with "deductive" reasoning from legal rules. Such a characterization presupposes that the facts of cases are first analyzed and then legal principles are "inferred" from such facts. However, the distinction between the facts of a legal case and the legal principle governing those facts is not the same as the distinction sometimes drawn between the facts of a laboratory experiment and the hypothesis offered by the scientist to explain the facts. The facts of a legal case do not have an existence independent of the theory of liability applied to them. A collision between X and Y may be a "fact" which natural science can "explain"; but whether or not X should be legally liable to Y, or Y to X, depends on whether or not X or Y was "negligent" or was carrying on an "extrahazardous activity" or was otherwise engaged in liability-creating conduct. Thus, as suggested earlier, the same kind of judgment that is required to determine the applicable legal principle (liability for harm caused by negligence, liability for harm caused by extrahazardous activity) is also required to characterize the legally operative facts (X drove negligently, X was engaged in an extrahazardous activity). To contend that since liability is imposed in situation A (for example, harm caused by collision of aircraft with ground structures, regardless of fault, air travel being considered an extrahazardous activity), and since situation B (for example, harm caused by automobile travel) is (or is not) comparable to situation A, therefore liability should (or should not) be imposed in situation B is an example neither of deductive nor of inductive reasoning, although it contains elements of each. It is an example of reasoning applied to reach decisions for action and, like the reasoning of a physician or an engineer or a politician, is based on a very large variety of considerations, many of which cannot be fully articulated.

Although reasoning by analogy is the primary form of legal logic, it is not sufficient in itself to compel particular legal results. There is, indeed, a large area of indeterminacy in all analogical reasoning, since the criteria for selecting similarities and differences are left open to debate. A rigid definition confining the term "logic" to those propositions that necessarily follow from given premises might therefore exclude analogy altogether. According to an old proverb, "For example" is not proof." Yet analogical reasoning, despite its flexibility, does impose limits upon legal results even if it does not in itself compel them. In each society some similarities and differences are so strongly

felt that they cannot be denied. Moreover, particular legal doctrines often restrict the range within which analogies may be found. Most modern legal systems, for example, require that a criminal statute be interpreted much more "strictly" than a statute imposing only civil obligations; similarly, courts are generally more reluctant to extend analogies under rules of commercial law than under rules of personal injury law, since commercial rules are relied on in business transactions where a high degree of stability and predictability is desired. In addition, each legal system establishes procedures and methods for drawing analogies—such as adversary and investigative procedures or the method of precedent and the method of codification—and these procedures and methods are designed to prevent analogical reasoning from becoming arbitrary.

Analogical reasoning is, of course, a universal mode of reasoning and by no means unique to law. What is distinctive about law, in this respect, is the degree of emphasis placed upon the use of analogy and the development of special legal rules, procedures, and methods for drawing analogies. For law the method of analogy has the special virtue—as compared with syllogistic reasoning—of exposing the examples by which consistency, continuity, and the weighing of opposing claims and defenses are tested.

Legal rhetoric. We define rhetoric, following Aristotle, as referring not only to the art of persuasion through appeals to emotions but also to the art of public deliberation through appeals to reason and hence as a mode of reasoning. At the same time rhetoric is distinguished from logic, since logic is concerned with indicative statements that are considered to be either true or false ("propositions"), whereas rhetoric is concerned with subjunctive, normative, and imperative statements uttered in order to influence thought or action. The classical formula of logic: All men are mortal, Socrates is a man, therefore Socrates is mortal—might be rendered in rhetorical form as: If you would be a man, O Socrates, you must prepare yourself for death!

Legal rules, being stated usually in the indicative mood, give the deceptive appearance of being only logical propositions; yet on closer analysis it is apparent that they have a rhetorical significance at least equally as great as their logical significance. The statement, for example, that the intentional premeditated killing of a person with malice aforethought constitutes the crime of murder in the first degree and is punishable by life imprisonment or death is not only a "true proposi-

tion" concerning what *is* murder (assuming it has been authoritatively declared); it is also a warning to potential murderers, an assurance to potential victims, a mandate to law enforcement officials, and, in general, an expression of the desires and beliefs of the political community. Legal reasoning with respect to the crime of murder consists, therefore, not only in the logical analysis of its definition, involving the comparison of various kinds of homicide (for example, homicide committed from motives of mercy, in self-defense, in the heat of passion, negligently, etc.); it also consists in both legislative and forensic rhetoric ("the death penalty should be abolished"; "the defendant is not a murderer") as well as in other, less formal types of argumentative speech (for example, "a person should certainly not escape responsibility for murder just because he believed his act would benefit society").

As the logical aspect of legal reasoning focuses attention on legal *rules* and on the principles to be derived from decisions in analogous cases, so the rhetorical aspect of legal reasoning focuses attention on legal *activities*. As many writers have emphasized, law itself is not simply, or primarily, a body of rules but an activity, an enterprise. A principal purpose of this enterprise is to subject human conduct to the governance of rules (Fuller 1964); but for that purpose rules must be drafted, debated, voted, published, interpreted, obeyed, applied, enforced—all of which legal activities involve the use of rhetoric and not only of logic. Moreover, apart from activities connected with rule making, it is also a purpose of the legal enterprise to render decisions, as by the casting of votes, the issuance of orders, the handing down of judgments; and the rendering of such decisions, like the making of legal rules, is both a product and an expression of rhetorical utterance. In addition, legal reasoning is directed to the negotiation of legal transactions, the making of petitions or recommendations, the writing of legal opinions, the issuance of legal documents, and to a variety of other types of legal activities, all of which involve the use of language to induce a response in those to whom the language is addressed.

As the use of analogy is a characteristic and pervasive form of legal logic, so the appeal to authority is a characteristic and pervasive form of legal rhetoric. The nature of the authority to which appeal is made differs in different legal systems. It is said, for example, that in traditional Muslim law the authority of the Koran is decisive and that only a literal interpretation of its provisions is permissible. In Judaic law, on the other

hand, with the development of the Talmud, there emerged the authority of leading rabbis who interpreted the Torah. In Roman law a similar authority was vested in leading jurists. We have already referred to the authority of judicial precedents in English and American law and of codes in modern continental European law. Probably the highest authority governing judicial decisions in most contemporary legal systems is that of statutes enacted by the legislature, although in the United States and some other countries the authority even of statutes must yield to that of constitutional provisions.

The appeal to authority in legal reasoning is not necessarily limited, however, to an appeal to legislation (whether embodied in statutes, codes, an authoritative book, or in a constitution), to judicial precedents, or to juristic commentaries on such legislation or precedents. In many legal systems—and perhaps in all—some room, at least, is left for appeal also to custom (that is, what is commonly done and what is commonly believed ought to be done) and to a sense of justice. Thus it is often said that there are four sources of law: legislation (including rules made by administrative authorities), precedent, custom, and equity. These four sources may also be viewed as four dimensions of law—legislation (and administrative rules) being directed to what should be done in the future, precedent being directed to what has been done in the past, custom being directed to outer social patterns and norms of behavior, and equity being directed to the inner sense of justice or fairness. Different legal systems, and different branches within a particular legal system, emphasize one or another of these four dimensions or sources or types of authority, and hence legal rhetoric is not uniform as between different legal systems or even within a single system. In American law, for example, the legislation-based rhetoric of a traffic regulation ("parked cars will be towed away") differs from the precedent-based rhetoric of a judicial decision ("this court has consistently held that the manufacturer is not liable to retail purchasers unless he is shown to have been negligent"); and both of these differ from the custom-based rhetoric of a negotiable instrument ("pay to the order of John Jones \$1,000") or the equity-based rhetoric of a divorce decree ("the father may have the child visit him four times a year for a week at a time").

Legal discourse. It is apparent that legal logic is itself a form of legal rhetoric. Legal rhetoric, in turn, is a form of legal discourse, whose functions go beyond that of influencing immediate thought

and action and include the preservation and development of the legal traditions and values of the entire political-legal community as well as the traditions and values of the legal profession itself in societies where a legal profession exists.

The distinctive characteristics of legal discourse arise principally from the institution of the *hearing*, which is the basis of all legal activities, including not only adjudication but also legislation, administration, negotiation of legal transactions, and other legal activities. It is the opportunity of both sides to be heard that principally distinguishes adjudication from vengeance. Similarly, it is, above all, the opportunity to debate pending enactments that distinguishes legislation from mere commands, and it is the opportunity to petition for relief that distinguishes lawful administration from bureaucratic fiat. Even a unilateral legal act such as the writing of a will requires the draftsman to put himself in the position of third persons who might be called upon to interpret the will in the light of a dispute over its validity or meaning.

A legal hearing involves two qualities of discourse that are not necessarily present in nonlegal procedures of listening and speaking. The first quality may be described as formality, that is, the use of a deliberate and ceremonial form of discourse, which usually is reflected in a formal presentation of claims and defenses, formal deliberation of the court or other tribunal, and the formal rendering of a decision. The formalities of the hearing help to secure its objectivity, that is, its impartiality, internal consistency, restraint, and authority.

A second distinctive quality of discourse characteristic of a legal hearing is the tendency to categorize the persons and events that are involved. The specific, unique qualities of the dispute are named in general terms. John Jones is called "the plaintiff"; Sam Smith is called "the defendant"; the defendant is alleged, for example, to have broken a "lease" by causing certain "damage" to the leased "premises." These are the "legally operative facts." The "real" facts—Smith's obnoxious personal habits, the neighbors' gossip, the family feud, etc.—are excluded unless they can be brought into relevant legal categories. This helps to secure the generality of the hearing. For the issue is not whether John Jones or Sam Smith is the better man but rather whether the rights of a lessor, rights established by the law of the community, have been violated by a lessee.

The formulation of the dispute or problem in terms of general categories, and thus the viewing of the concrete facts *sub specie communitatis*, is

organically derived from the hearing, although it is logically distinct from it. The dispute or the problem has challenged the existing legal rules; the parties have invoked a reformulation of them in the light of the concrete facts; and the court (if it is a judicial proceeding), or legislature (if it is a proposed statute), or administrative agency (if it is a new regulation that is sought), or lawyer (if it is a contract that is being negotiated or a will that is being drawn) is asked to reinterpret the existing rules or to create new rules in the light of the new dispute or new problem. Categorization of the specific, unique facts, carried out in the context of a deliberate and ceremonial presentation of claims and defenses with a formal procedure for interrogation, argument, and decision, helps to secure the generality and objectivity not only of the hearing but also of the reinterpreted or newly created rules and hence their acceptance by the community. At the same time, the legal vocabulary and techniques that are generated in this process provide a professional shorthand or jargon that is designed to contribute to the efficiency of legal procedures or to the fraternity of the legal profession, or to both, although it often has the effect of making both law and lawyers seem alien to the society that has produced them.

The circularity of legal reasoning. If law is seen, in the first instance, not as rules but as the enterprise of hearing, judging, prescribing, ordering, negotiating, declaring, etc., then it becomes possible to give a satisfactory explanation of what Jeremy Bentham called the tautology and circuitry of legal terms and what H. L. A. Hart calls the "great anomaly of legal language—our inability to define its crucial words in terms of ordinary factual counterparts" (1953, p. 41). It is, indeed, true that legal reasoning characteristically appears to be circular. When it is said, for example, that a man has a "right" to something because someone has an "obligation" to transfer it to him, the "right" of the one and the "obligation" of the other seem to be merely two different terms for the same thing. Similarly, the word "crime" and the word "law" themselves seem to be only alternative ways of saying "right," "obligation," etc. Bentham wrote:

Each of these words may be substituted the one for the other. . . . The law directs me to support you—it imposes upon me the *obligation* of supporting you—it grants you the *right* of being supported by me—it converts into an *offence* the negative act by which I omit to support you—it obliges me to render you the *service* of supporting you. . . . This, then, is the connexion between these legal entities: they are only the law con-

sidered under different aspects; they exist as long as it exists; they are born and they die with it. . . . The legal terms seem to have no "empirical referents"—no "things" to which they "correspond." (*Bentham's Theory of Fictions*, pp. cxxix–cxxx)

The proliferation of interdependent legal terms referring to the same thing is due to the fact that the terms are not supposed to "refer" to "things" but instead to regulate a complex interrelationship of people engaged, actually or potentially, in legal activities of various kinds. From the standpoint of the child, support is a "right"; from the standpoint of the parent, it is an "obligation"; from the standpoint of the prosecutor, failure to fulfill the obligation may be a "crime." It is true that if there were no right there would be no obligation and no crime, and if there were no crime there would be no obligation and no right (or at least a different kind of obligation and right). But these (and many other) terms are needed to identify the complexity of the relationship between the child, the parent, and the state; they are needed especially when the relationship is described in abstract terms. The decision of the court may be simple enough: "Pay \$25 a week for support of the child or go to jail."

It may seem senseless for courts or writers to go (as they sometimes do) from right to obligation to penalty as if in a logical sequence. Yet what may be senseless as a logical proposition may be sensible as a means of identifying the parties to a dispute and the nature of the disputed issue. To attack legal rules as question-begging is itself to beg the question of their function. Indeed, in some cases it is the function of judicial tautology and circularity to avoid giving a reason for a decision in a situation in which it is better to give no reason than to give the real reason. This is apt to be especially true of legal fictions, which are legal doctrines that state a legal result in terms of assumed facts that are known to be nonexistent. Here what are understood to be only analogies are consciously treated as identities, in order to preserve consistency of doctrine in the face of an unexplained inconsistent result. For example, a battery is traditionally defined as an unpermitted blow which the defendant intended to inflict on the plaintiff, but the courts nevertheless give a recovery to a person whom the defendant struck unintentionally while intending to strike another, applying the fiction that the defendant's intent to strike the third person is "transferred" to the person whom he in fact struck. Thus the original definition is preserved in form but its consequences are changed. In most cases, however, legal

tautologies and circularities are not intended to change the consequences of legal rules but are primarily a means of specifying the various aspects of legal relationships, often for procedural reasons. In any event, not only circular but also other "unscientific" qualities of law may often be understood if they are seen as part of the logic of analogy, the rhetoric of appeals to authority, and the discourse of formality and categorization that are the distinguishing characteristics of legal reasoning.

Legal reasoning and social science. Despite important insights into the nature and functions of legal reasoning contributed by such classical sociologists as Émile Durkheim and Max Weber (both of whom were legally trained), modern social science has left the subject largely to legal scholars. However, recent sociological studies of the professions have, following Weber, related legal reasoning to the need of the legal profession to have its own professional language; and in the last two decades many American political scientists have attempted to debunk legal reasoning as a disguise for judicial decisions reached on the basis of non-legal considerations. More important, probably, at least in the long run, are studies by social scientists not of legal reasoning as such but of legal institutions, such as the jury system, civil rights legislation, criminal law enforcement, collective bargaining, the antitrust laws, etc., since such studies provide a necessary foundation for any generalizations about the relationship of legal reasoning to other types of reasoning. In the meanwhile, studies of legal reasoning by legal scholars—who are also social scientists—will continue to benefit from social science theories and methods directed to the study of social institutions generally, including legal institutions. Indeed, social science theories and methods sometimes have a direct impact on legal reasoning itself when they are introduced into legal proceedings through, for example, legislative hearings and, occasionally, court cases in which social scientists are called in as experts.

Social sciences other than law may, however, have more to learn from an understanding of legal reasoning than they have to contribute to such an understanding. Since law is a practical social science, in which principles of order and justice accepted by a given society are applied to the reaching of reasoned decisions for action, the legal profession (including legislators, judges, administrators, and legal scholars, as well as practicing lawyers) is highly sensitive to the relationship between theory and practice, and, more specifically,

to the relationship between reasoning and the social context in which it takes place. Thus legal experience not only provides a wealth of data for investigation by social scientists but also has much to teach them concerning the nature of social science. Indeed, legal reasoning challenges the belief that any social science can properly avoid the question of its applicability to society; it challenges, therefore, the theory of a "value-free" social science based upon the methods of the physical sciences or of mathematics. Such a challenge is inherent in the emphasis which law places on the connection between what is said and the role of the speaker, as well as in the assumption implicit in law that a judgment affecting persons is not merely an observation or measurement of external facts but also a response to the language addressed to the person making the judgment, and that a proper judgment is itself addressed to the participants in the proceedings in which it is made.

COMPARATIVE LAW AND LEGAL SYSTEMS

Laws are different in different countries and often within the same country. This fact has given rise to that branch of jurisprudence which is known as comparative law (*Rechtsvergleichung*; *droit comparé*).

Precursors

While laws have been different through the ages, sustained scholarly concern about their diversity is hardly one hundred years old. An occasional interest in the diversity of laws has, of course, been shown every now and then, but systematic studies had their origin in the 1860s.

Comparative law could not be developed as a field of learning before the various local laws had come to constitute subject matters of academic learning. On the continent of Europe that was not the case until the high Middle Ages; in England it did not occur until the nineteenth century. But even the development of scholarly pursuits in the several legal systems did not immediately result in their comparative treatment. In fact, the way legal learning developed on the European continent constituted a hindrance to comparative observation.

The legal learning of the Roman Empire was lost in the barbarian invasions. In the course of the Middle Ages the crude customs of the Germanic invaders developed into bodies of law of considerable complexity and refinement, but they developed as customs of local courts of manifold kinds rather than as bodies of law that would be cultivated and elaborated by scholars. In England, the only medieval country where, in consequence of the Conquest, the growth of the law began to be centralized in the courts of the king, the law specialists were craftsmen rather than academic

teachers and scholars. Only canon law, the law of the church, was given some attention by the scholars who came to gather in the emerging universities. A change occurred when Roman law was rediscovered and, from the twelfth century on, made the subject matter of academic teaching and writing, first in Bologna and then in the other rapidly growing and increasing universities. By the successive schools of the glossators (twelfth century) and post-glossators (thirteenth and fourteenth centuries), the humanists (sixteenth century), the Dutch and French jurists of the seventeenth and eighteenth centuries, the rationalist school of natural law, and, ultimately, the German Pandectists of the eighteenth and nineteenth centuries, the Roman law was transformed into the so-called civil law, which was taught in all the universities and was elaborated in scholarly treatises and dissertations, but which was not practiced anywhere in the form in which it was taught. The law that was actually applied in the courts was an amalgam of the civil law and local customs and statutes. The civil law of the scholars was thought of as a body of rules and principles of universal validity. The law in action differed from place to place. It was rarely regarded as worthy of the attention of the scholars. The law with which they were concerned was uniform. There was nothing with which to compare it. If views of the law differed, only one of them could be right. The actual laws that could have been compared were too limited in their spheres of application. What little comparative attention was paid to them was limited to a dry enumeration of differing rules. Even the great codifications of private law in Denmark-Norway (1683-1687), Sweden (1734), Prussia (1791-1794), and Austria (1811) evoked little interest on the part of the scholars. In France, on the other hand, Napoleon's codes (1804-1810) established themselves so firmly as the subject matter of professional treatment that the old civil law disappeared from the curriculum. The same concentration on new nationwide unified laws took place in consequence of the later codifications in Germany (1896), Switzerland (1907), Italy (1865-1942), and other countries. The vast task of expounding and elaborating the contents of the new codes absorbed the energies of the scholars. In each country legal science came to be nationalized in the sense of being nationally isolated. Scholars would look beyond the national borders only insofar as the national codification had been modeled upon that of another nation. French legal learning was thus

looked to in Italy, the Netherlands, Spain, Latin America, and those other countries in which Napoleon's codes had served as models. German legal learning was influential where the local codes or laws had come under the influence of German scholarly writing, as in Austria, Switzerland, Scandinavia, and Japan.

In both periods, that of the civil law and that of the codes, Continental legal learning was primarily interested in "dogmatics." Starting with an authoritative text—in the civil-law epoch that of the *corpus juris* and in the later period that of the respective national code—the scholars busied themselves with the "interpretation" of these texts. The law laid down in the texts was regarded as being complete, that is, as providing the answer to every problem that would ever arise, provided one would only read and understand the text in the right way. Legal science was the science of properly interpreting the texts, just as theology consisted in the interpretation of the Scriptures. Under such an approach there was as little room for, and interest in, comparison of laws as there was in the comparison of religions.

In England the situation was similar but for different reasons. The centralized, well-organized, and politically powerful English bar had succeeded in resisting the onslaught of the Roman law. In the royal courts at Westminster, the various local customs were welded into the common law of England. The elaborators of the law were the practitioners, especially the judges. They were craftsmen, not academicians. English law was hardly taught in the universities; one learned it in apprentice fashion, by doing. To learn the practice of some outlandish law, say, of Scotland, was for the English lawyer of as little interest as it would have been for a shoemaker to learn carpentry.

Lawyers are not the only people interested in law. The law also attracts the interest of theologians, philosophers, and those who in English-speaking countries have come to be called jurists, that is, scholars who know the law and yet are interested in it not from the strictly professional point of view but from that of one who looks upon the law, so to speak, from the outside. The jurist is the man who is interested in the law's growth in history, in the values which it protects and promotes, in the machinery through which it functions, in the structure of its body, and in its role and functions in society. It was among philosophers and jurists that interest in comparative law was first exhibited. It is among sociologists, anthropologists, and political scientists that such interest

is presently growing; but attitudes are changing also among the lawyers, especially the legal scholars. They have begun to develop a new jurisprudence within which comparative law is coming to play a constantly increasing role.

Among the precursors of modern comparative law students one might mention Aristotle, who engaged in the comparison of the constitutions of the Greek city-states. In the Middle Ages some canonist, legist, or theologian every now and then engaged in comparative observation of secular law and canon law. In later times the peculiar features of the law merchant attracted some attention.

Suddenly there appeared Montesquieu, almost without predecessor—and also to be without immediate successors. In *The Spirit of the Laws* (1748), the law is treated as a social phenomenon and the diversity of the laws is seen as being caused by diversities of the natural, historical, ethnical, political, and other factors of the social setting. In the early part of the nineteenth century, Montesquieu's ideas reappeared in the thinking of Hugo, Savigny, Eichhorn, and the other writers of the German historical school. In reaction to the natural-law jurists' belief in the possibility and desirability of a system of law that could be developed by reason and would be valid universally, they again emphasized the dependency of the laws upon the surrounding conditions, especially the peculiar spirit of each nation (the *Volksgeist*). Divided into the two hostile camps of Romanists and Germanists, the men of the historical school endeavored to replace the amalgam of Roman and Germanic traditions that characterized the *usus modernus pandectarum* by new systems of revitalized Roman or Germanic law. Comparisons between these two systems were, of course, incidental to the heated debates, and some attention had to be paid to the law of France, in which Germanic traditions had survived to a larger extent than in Germany, and to the laws of England and Scandinavia, where no wholesale reception of Roman law had taken place. Institutions of English public law had attracted attention ever since their praises had been sung by Montesquieu, and they were widely imitated on the Continent in the course of the revolutionary movements that were sparked by the events of 1789.

Montesquieu's insight into the interdependency of the law and other social factors was applied again by Sir Henry Maine, who was struck by similarities between the laws of ancient Rome and of India and by parallels in their development. Influenced by the Darwinist thought of his time, he ventured in his *Ancient Law* (1861) to formu-

late his famous "law" of universal sociolegal development from status to contract.

Modern comparative law

The interest of lawyers rather than jurists in the field of modern comparative law began with the foundation of the Société de Législation Comparée in 1869, the establishment of the Comité de Législation Comparée in the French Ministry of Justice in 1876, and the founding of the English Society of Comparative Legislation in 1898. The movement had its origin in practical considerations. It was believed that the ideas and experiences of foreign countries, especially new foreign legislation, should be made available for one's own national law making, which in the spirit of the time was identified with legislation. Translation and discussion of new foreign codes and laws thus constituted the principal field of activity of the small circle of interested specialists.

Comparative law rather than comparative legislation came to appeal to a widening circle of scholars in connection with the late nineteenth century's optimistic belief in the desirability and possibility of large-scale international unification of private law. Along with public and private international law, comparative law thus figured among the topics discussed at the annual meetings of the Institut de Droit International. The ideal of international legal unification also was the inspiring motive of the great international Congress of Comparative Law, held in Paris in 1900. With its large assembly of scholars from all over the world, the congress lived in the memories of the participants as the high point of what is nostalgically called *la belle époque du droit comparé*. From then on the work in the field grew more realistic. The development is reflected in the life work of Édouard Lambert, whose institute of comparative law at the University of Lyon (founded in 1920) constituted for some decades the center of painstaking, detailed research.

Practical interest in knowledge of law for purposes of legislation, international unification, and everyday law practice in international transactions, commercial and otherwise, continued to stimulate steadily increasing interest in the study of foreign laws. There also grew up new theoretical interest. The desire to discover the beginnings of the development of law as a general social phenomenon—a development which was widely regarded as having proceeded more or less unilineally—drew attention beyond Roman, Greek, or Germanic law to laws of more archaic character, as well as to the customs of primitive peoples. This new interest

in "ethnological jurisprudence" and related matters was given a focus in the *Zeitschrift für vergleichende Rechtswissenschaft* (begun in 1878).

The more comparative law assumed the character of a social science, that is, a pursuit of systematic knowledge about law as a social phenomenon the study of which would have to reach beyond national boundaries, the more the workers in the field became aware of its difficulties. Where could one find a library containing all the necessary materials? What human mind could retain and organize them? A decisive step was taken in 1917 with the establishment of Ernst Rabel's institute of comparative law at the University of Munich and, nine years later in Berlin, the Kaiser Wilhelm (now Max Planck) institutes for foreign and international private law (now in Hamburg) and also for foreign and international public law (now in Heidelberg). At these institutes a comprehensive library was established, and there was assembled a team of specialists, who under Rabel's direction would advise drafters of new legislation and participants in international legal life and who would systematically observe legal developments the world over in order to gain theoretical insights and develop new methods of legal thinking and research. The impact of the innovation has been far-reaching. The establishment of the comparative law institutes coincided with and strengthened the change in method of German legal thought from conceptual-analytical jurisprudence to the new method of jurisprudence of interests with its emphasis upon knowledge of the facts of social life and of socially current evaluations of conflicting interests. Under such a method, limitation of scholarly concern to the phenomena of one's own nation is no longer possible.

The simultaneous shift in legal method that occurred in the United States was a principal cause of the rapid growth of American interest in comparative law or, as it is now frequently called, international legal studies. The growing involvement of the United States in world affairs, political and commercial, was another powerful motive.

Scholars like Roscoe Pound, John H. Wigmore, Ernst Freund, and H. W. Millar had been working since the turn of the century at breaking through "Mainstreetism" toward world-mindedness in legal learning. Their breadth of learning is reflected in the scope of their own work as well as in the Legal Philosophy Series, the Continental Legal History Series, and the Modern Criminal Science Series, which they promoted and edited. Effectively supported by the Ford Foundation, international legal studies have, since World War II, come to consti-

tute an essential part in the curriculum and the research programs of American university law schools. Cooperation with sociologists, economists, political scientists, anthropologists, and historians is being sought by the law scholars. What is still lacking in the United States is a great research institute on the pattern of the German Max Planck institutes.

In the United Kingdom, the study of comparative law was pioneered by Harold C. Gutteridge. It is now finding its place in the universities, where academic teaching of the law has come at a rapidly increasing pace to supplement, or to take the place of, the old-fashioned apprenticeship training. A center for research is provided at the Institute of Advanced Legal Studies in London, established in 1948.

In France, courses on the great legal systems of the world are offered at the university law schools; research is promoted through institutes, especially in Paris, Lyon, and Toulouse. In Italy, interest in comparative law is vigorously cultivated at a number of universities. Institutes and university faculties in Spain, Latin America, Scandinavia, Japan, Yugoslavia, and other countries are also active. In the Soviet Union, foreign legal developments are closely observed in the law institute of the Academy of Sciences.

Comparative law, being supranational, calls for international cooperation. An organizational instrument for cooperation is provided by the International Association of Legal Science, which is affiliated with UNESCO, and through its directorate, the International Committee of Comparative Law. International meetings of comparatists are sponsored by the International Academy of Comparative Law. Instruction is offered by the International Faculty for the Teaching of Comparative Law, which has its seat in Strasbourg, and the International University of Comparative Sciences in Luxembourg.

Methods and scope

In comparative legal research one may distinguish between micro-comparison and macro-comparison. The latter is concerned with the comparison of entire legal systems, such as the Anglo-American common law and the so-called civil law, or, within the civil law, the family of the so-called Romanist laws, that is, those based on the French and German patterns. Micro-comparison is concerned with detailed legal rules and institutions. The two approaches, of course, shade into each other, especially in the comparison of methods of procedure and of legal thought.

Micro-comparison. In the earlier phase of the study of comparative law one tended to start out from particular institutions. One would, for instance, compare contract in Anglo-American and in civil law, or possessions in French and in German law, or the common-law doctrine of consideration and the civil-law concept of *causa*. In such a process one made two important discoveries: first, that seemingly identical terms rarely have the same meaning in different legal systems; second, that the same, or seemingly same, institution might perform different functions in different surroundings. The meaning of the Anglo-American term "contract," for instance, was found to differ in several respects from the term "contractus" of Romanist terminology and its modern counterparts. The institution of damages for tort was found to have a strictly compensatory function in German law, but both a compensatory and a punitive function in the common law. Thus, comparatists have increasingly come to incline toward the functional approach. Instead of starting with any particular rule or institution, one starts with a social problem and seeks to discover the rules or institutions by means of which the problem is resolved. What devices are, for instance, employed in different laws to provide for the orderly payment of the debts of a dead person, or to provide relief for the victims of unfair or sharp practices in business deals, or to provide for the security of title of purchasers of real estate? Such investigations are likely to indicate that, on the one hand, devices of considerable variety have been and can be used to achieve more or less identical purposes but, on the other hand, that the catalogue of technical devices available to legal designers is not unlimited.

Macro-comparison. Macro-comparison of entire legal systems has sought, in the rare case of Max Weber or in such modern surveys as that of René David, to cover the world. Mostly, however, it has been concerned with the two great systems of Western civilization, the Anglo-American common law and the civil law.

Common law versus civil law. Close inspection has shown that the characteristic differences between common law and civil law ought not to be expressed in the frequently used antitheses of codified versus uncoded law, or of statute law versus judge-made law, and even less in that between authoritarian versus libertarian law. Large sections of the law of civil-law countries, for example, the bulk of French or German administrative law, are neither codified nor even expressed in statutes, while big portions of English and

American law have been brought together in comprehensive statutory codifications, as, for instance, the maritime and commercial laws of the United Kingdom or, in the United States, the uniform commercial code and the U.S. code of internal revenue. There exist, it is true, differences in the judicial attitudes toward such codifications, but they have their basis in that difference between the two great systems which is essential, namely, the difference between methods of legal thought.

The role of judicial precedent also differs less in the two systems than it was commonly believed to do. In theory, a common-law judge is bound by precedent, while a civil-law judge is not only free to ignore it but is supposed to take a fresh look at every individual case. In fact, judges in France or Germany pay such careful attention to precedent that entire sections of the law are judge-made, such as the French law of torts or that large body of German law which determines in great detail the commands of good faith and fairness which contracting parties are to observe toward each other. The older the code—the French civil code is 160 years old, the German civil code is about 70—the greater is the weight of the judicial gloss by which the text is overlaid. Common-law judges, on their side, are as well versed as their Continental brethren in the fine art of distinguishing upon the facts a new case from an unconformable precedent. Besides, in contrast to British courts, American courts no longer shy away from openly overruling a precedent that is regarded as no longer suitable.

As to the alleged contrast between civil-law authoritarianism and common-law espousal of liberty, it suffices to indicate that Switzerland is a civil-law country and Ghana is a common-law one, as was England in the days of Cromwell. And finally, it is a myth, though apparently an ineradicable one, that in civil-law criminal procedure the accused has to prove his innocence.

The essential difference between common law and civil law lies in the technical structure of court procedure, in the different conceptual framework within which legal thought moves, and in the underlying cause of these differences: the diversity of the personnel by which the machinery of the administration of justice is handled and guided.

Perhaps the most far-reaching discovery that has been made in comparative law research is Max Weber's observation that the climate of a society's legal system is ultimately determined by the kind of people by whom it is dominated, that is, as Weber calls them, the *honoratiors* of the law (1922). It makes a difference whether a legal

system is dominated, as that of classical Rome, by gentlemen of leisure and high-ranking administrators, or, as the Islamic, by theologians, or, as the classical Chinese, by philosopher-bureaucrats. The common law grew up as the law of one set of centralized courts that was staffed with a small elite judiciary; this judiciary, in turn, was linked to that closely knit centralized bar from which it was drawn. The resulting common law reflects these surroundings: the mode of reasoning is that of analogy—policies are not always followed with consistency, nor are concepts always clean-cut; the law is thought of less as a body of norms of social conduct than as a set of rules of decision for the relatively few disputes that cannot be settled extrajudicially. Occasional obsolescence is not necessarily regarded as a serious evil, but, in general, those ex-barristers who occupy the bench are close to the course of affairs and know how to decide a concrete case that is presented to the court in oral contradictory trial by the members of a highly experienced bar.

What was decisive on the Continent was the absence of one central court. If the law was to keep abreast of changing conditions and to preserve a minimum of uniformity, guidance had to be exercised by the university law faculties, whose members for centuries constituted a supralocal community. Interpreting the book that was thought to constitute the theoretical basis of the law, they tended toward systematic arrangement, the elaboration of great principles, the logic of the syllogism, consistency of terminology, and an occasional remoteness from life. Efforts to adapt the law to changing social conditions were apt to be hidden behind controversies as to what should be the right interpretation of the authoritative text. Law being thought of as a set of rules of human conduct, it tended toward paternalistic guidance by those who would know best—the professors and the high-ranking officers in the service of the princes.

Today the scene has changed. On the Continent the establishment of central national courts has given great power to the judiciary, with a corresponding decline of the once leading role of learned doctrine. In the United States, on the other hand, the influence of the professors of the national law schools has come to be powerful in those branches of the law for which no uniform case law is created by a court of nationwide jurisdiction, that is, for all law other than that of the constitution of the United States and the body of federal statute law. With the breakdown of the centralized appellate jurisdiction of the Judicial Committee of the Privy Council, a similar develop-

ment has occurred in Britain. Legal education is being taken over by the universities, and their professors are becoming guides for the judges of the courts of England and the Commonwealth countries. These courts are now as independent of each other as the state supreme courts in the United States are and as the courts of the small jurisdictional units of the Continent once were. Subtle changes in the character of the law, substantive and procedural, are the consequence of these developments in both systems.

Socialist law. In macro-comparison of legal systems, much attention has recently been paid to the laws of the socialist countries, especially the Soviet Union. Western observers have raised the question of whether these laws constitute a legal system of their own or whether they should be regarded as a branch of the civil-law system. The answer depends upon what test one applies. If one looks to the content of the legal rules and the machinery by which they are administered, one will agree with the Soviet jurists that their laws constitute a system of their own, even if one regards the difference between socialist law and "bourgeois law" as less enormous than it is made to appear in Soviet theory. After all, the welfare-state idea has taken hold in Western countries. If, on the other hand, one looks to the conceptual framework of the law, especially as it appears in the codes, or if one is interested in the basic features of court organization and procedure, a lawyer trained in French, German, or Swiss law will find his way more easily than one trained in the common law. If one looks to the personnel of the administration of justice, he will observe attitudes considerably different from those of Western judges and lawyers, but he can also observe among his Eastern brethren a steadily growing tendency to look upon themselves as guardians of individual rights against arbitrariness.

The tasks of comparative law

The careful analysis of legal systems that is now being elaborated has resulted in a distrust of timeworn clichés. Even the distinction between common law and civil law must, we have learned, not be overestimated. It is a difference more in method and traditions than in content. Also, it applies more to private than to public law. The forms of democratic government and the legal devices to secure the citizen's participation in government and his protection against abuses of governmental power, democratic or authoritarian, are independent of the historical background of legal development.

Comparative law impressively demonstrates the unity of Western civilization, which has spread over the world and is transforming the once different civilizations of the East. Western laws have come to be the laws of Asia and Africa. They are influencing even family law, in which non-European traditions have held out longest. Except for disappearing traditions of family law and matters related thereto, there is now in the world not a single country whose law would not belong to one of the three systems of Western origin: civil law, common law, socialist law.

In both micro-comparison and macro-comparison, the comparatist has to do more than merely ascertain differences and similarities of legal norms and institutions. If he wishes to learn about the reasons he must investigate the social conditions under which the norms and institutions of the law have originated, under which they operate, and which they influence. The legal comparatist must become a social scientist. The difficulties of the task, which are already formidable in a strictly formal comparison, are multiplied. No wonder that performance has been lagging. However, beginnings have been made in micro-comparative as well as in macro-comparative studies, especially of subjects of private law and procedure.

The great creators of law have always been observers of social reality. The classical Roman jurists who patiently elaborated the legal norms which are necessary for the smooth functioning of an economic order of free enterprise were consistently engaged in what we today call social research. Medieval canonists sound like modern sociologists when they observe that papal efforts to suppress blood feuds by means of law had to fail because such means conflicted with the mores of the people. The ever-recurrent tendency of lawyers to regard law as a self-sufficient body of rules was carried *ad absurdum* by Montesquieu, Savigny, and such more recent legal scholars as Rudolf von Jhering, Henry Maine, Frederic W. Maitland, Otto von Gierke, and François Gény.

In the new jurisprudence of the mid-twentieth century, as it has been developed simultaneously in the United States (Roscoe Pound, John H. Wigmore, Karl Llewellyn), in Germany and Austria (Eugen Ehrlich, Max von Rümelin, Philipp von Heck), and in Scandinavia (Anders Vilhelm Lundstedt), and which is now tending to become as universal as the jurisprudence of concepts was in the latter part of the nineteenth century, the science of law has become a social science.

II

COMMON LAW SYSTEMS

The term "common law" is used in a number of different senses. In medieval English law it denoted that law which was administered by the king's courts and which was, in principle at least, common to the whole realm. The common law, in this sense, was to be distinguished from the law administered in the local, county courts or in the feudal, barons' courts, which tended to be specialized or particularized by region; and it was also to be distinguished from autonomous bodies of law, like the law merchant, which were peculiar to certain classes of persons.

In another sense, however, the common law is set in opposition to statute law. The common law is rendered concrete and explicit in, and derives its juridical efficacy from, decisions of courts; whereas statute law, or legislation, is an emanation of the will of the sovereign parliament or legislature. In this same specific sense, the common law is also distinguished from codified law or code law (civil law). The common law is conceived of as a body of principles originally derived from customs which are either reflected in the judgments of the highest national courts or else contained in piecemeal statutes passed *ad hoc* to correct or extend those same decisions. Thus it is opposed to those systems of law which have been reduced to more or less permanent written form and organization through a single comprehensive piece of legislation or codification.

Insofar as the English-speaking countries have generally been able to resist comprehensive codification of their laws, we are led into the broadest and most popular meaning of the term common law—the law of the English-speaking countries as opposed to the (generally codified) civil law of continental Europe and of those countries in Latin America, Asia, and Africa that were politically influenced by, and whose legal systems were shaped by, continental Europe.

In yet another sense, the common law is opposed to equity—that body of law, distinct from the common law, which was administered by the lord chancellor, as "keeper of the king's conscience," through the chancery courts, in order to correct or ameliorate the harshness or rigidities of the common law as administered by the regular courts. Equity started as a series of principles and rules, reflecting considerations of fairness and natural justice, which were, in medieval times, of such flexibility and range as to warrant the latter-day charge that equity was "as long as the chancellor's

foot." By the early nineteenth century, however, it had jelled into a fairly rigid system of precedents and judicial authorities distinguishable from the common law mainly in that it was administered by a separate judicial hierarchy, the chancery courts. The Judicature Acts of 1873–1875, which effected a wholesale organization of the English judicial structure, abolished the special chancery courts, and equity was formally fused with the common law into a single system of precedents administered by one system of courts.

Last, the term common law is sometimes used to denote the private law, i.e., that body of law governing relationships of private citizens *inter se* in which the public or state interests are normally minimal or else only peripheral (for example, the law of contracts, torts, personal property), in contradistinction to constitutional law and public law generally (for example, administrative law, labor law, antitrust law) in which the public interests are normally pervasive. This distinction is ceasing to be really meaningful in modern terms, as the state increasingly intrudes into areas of law originally considered as involving personal interests only.

Diffusion of the common law. It is true of the common law that English settlers proceeding overseas to found new colonies carry with them the law of England existing at the time of the first settlement, except insofar as that law may be obviously inapplicable to the new area. For example, the old common law rule of "ancient lights" might be considered inappropriate or unnecessary in newly settled areas without any tall buildings and therefore inapplicable and not automatically "received" as law on settlement. Through this device, whereby new content and meaning were poured into old formulas, the common law became the basic law of the United States and of those Commonwealth countries founded by settlement. In the case of those parts of the British colonial empire acquired by military conquest and already having a local population (indigenous people or non-British settlers), different principles were applied, usually involving the maintenance of the local private law, as, for example, in the case of India, South Africa, and the Province of Quebec.

Once the English common law was "received" into an overseas colony, it continued in force until such time as it was repealed, altered, modified, or added to by appropriate constitutional authority—whether by the British Parliament as the supreme imperial legislative authority, or by the Privy Council sitting in Westminster as the final appellate tribunal for the overseas empire, or by the

colonial legislature and colonial courts acting within their respective jurisdictional limits and competence and subject to appropriate control by imperial constitutional agencies. These imperial controls disappeared, in the case of the American colonies, with the Declaration of Independence; and they virtually disappeared in the case of the self-governing Commonwealth countries with developing constitutional custom and convention. This was partly confirmed and recognized in statutory form with the Statute of Westminster (1931), a British statute, although some members of the Commonwealth (Australia and New Zealand, for example) still retain, by their choice, an appeal from their courts to the Privy Council. Insofar as the common law remains the basic private law of the various English-speaking countries today, it is by those countries' own decisions to maintain and even extend their historical legal inheritance. For these purposes it becomes necessary to consider the juridical institutions and techniques whereby the common law is applied and developed in these countries.

Institutions and techniques. The key element in the continued viability of the common law today is undoubtedly the existence of the *doctrine of precedent*. This doctrine establishes, first, the obligation of court jurisdictions to adhere to and apply the decisions of tribunals that are superior to them in the judicial hierarchy; and, second, the principle that the highest court in the land is bound by its own decisions. The first aspect seems obvious enough, since it is a natural consequence of the pyramidal structure of court organization in England and has the practical utility of ensuring uniformity and predictability of decisions by inferior and intermediate tribunals. The second aspect—the principle of *stare decisis* in the strict sense—although often regarded as a truism of common law jurisprudence, was actually formulated as a binding principle of the English common law only in 1898, in the London Tramways case decision. Since that time, however, it has been one of the major preoccupations of common law legal theory.

Quite apart from the issue of whether courts ought to be bound by past decisions, the "legal realist" school, which was very influential in American law schools in the period between the two world wars, raised the issue of whether courts, as a matter of *fact*, did bind themselves by past decisions. Led by such brilliant young scholars as Judge Jerome Frank and Karl Llewellyn in the early 1930s, the legal realists pointed to the substantial devices or stratagems available to courts to mitigate the effects of unwanted judicial deci-

sions from earlier eras. Among these devices the legal realists identified the practice of "distinguishing" prior cases: focusing on assertedly new or different fact situations in the case before the court, in contrast to the fact present in those earlier cases that established the now unwanted principles of law. The legal realists also pointed to the widespread judicial inclination toward "shading" of earlier decisions, that is, giving some more weight than others by categorizing them as the decisions of "strong courts" or by focusing on individual judicial opinions, separate and distinct from the official opinion of the court, in cases in which more than one judicial opinion is filed. These individual opinions could be special concurring opinions or even dissenting opinions in the case of "prestige" jurists like Oliver Wendell Holmes of the United States Supreme Court. Opinions of the intellectual caliber and clarity of Holmes's great dissent in the *Lochner* case in 1905 became appeals to the future and were later expressly vindicated by United States Supreme Court majorities, as in *West Coast Hotel Company v. Parrish Company* (300 U.S. 379) in 1937.

It must be admitted that "distinguishing" prior decisions is immensely facilitated by the proliferation of individual opinion writing on final appellate tribunals in the common law world. Only the Privy Council, among these courts, still resolutely adheres to its practice of filing only a single *per curiam* opinion in each case.

The "distinguishing" of cases is also assisted by the plethora of separate common law jurisdictions of the present day, each turning out its own decisions. Consider the problem in the federal states of the English-speaking world. In the United States there are 50 autonomous private law jurisdictions; each is theoretically independent and separate from the other, and the supreme court of each state is the final appellate tribunal for cases arising there (except insofar as those cases also raise issues involving federal jurisdiction). Although the decisions of any one state supreme court are not, of course, binding on any other state, they may have a certain persuasive authority, and it is frequently possible to find lines of opposing decisions from different state supreme courts, thus opening up the way for a creative judicial choice—judicial policy making. Notwithstanding the 50 separate, and at times competing, state private law jurisdictions there are countervailing forces that point toward the unity of the common law in the United States. There is, first, the *Restatement of the Law* prepared by the American Law Institute (1953–1965). Although not "official," it brought together

the best experts available (law professors, judges, and lawyers) and soon achieved a quasi-official status. The *Restatement* tried to present the consensus of private law among the then 48 states and thus performed an important unifying function among the 48 jurisdictions. It still enjoys high respect in most state courts. Another important unifying factor is the existence of great "national" law schools (Yale, Harvard, Columbia, Chicago, etc.), which consciously avoid stressing the law of their own particular state and can thereby teach a genuinely "national" common law that can draw on the best principles of the jurisprudence of the 50 separate state systems.

Emphasis upon the "distinguishing" of cases on the facts directs attention to the crucial role of facts in contemporary common law decision making. It is not merely that the orthodox view of the principle of a case (or *ratio decidendi*) is the rule enunciated by the judge plus the material facts in the case (Goodhart 1931). It is also that, under the influence of legal realist teachings, courts, in accepting the desirability and inevitability of judicial policy making (or judicial legislation) at the final appellate level, have increasingly accepted the desirability of having an adequate factual record in aid of such judicial legislation. This new emphasis has perhaps received its fullest outlet in American jurisprudence in the so-called "Brandeis Brief" method of adducing constitutional facts to the notice of the United States Supreme Court; but it has also had its effects in the private law.

It is in American constitutional law, of course, that the direct and avowed departure from the principle of *stare decisis* has been most marked, prompting Judge Owen Roberts to comment ruefully, on the overruling of earlier United States Supreme Court decisions, that this trend to court flexibility tended to "bring adjudications of this tribunal into the same class as a restricted railroad ticket, good for this day and train only" (*Smith v. Allwright*, 321 U.S. 649, 1944).

The common law and social change. The contemporary judicial disposition to depart from *stare decisis*—either by directly overruling past decisions or by "distinguishing" cases—emphasizes movement and growth in the positive law as the society in respect to which the positive law is to operate itself changes.

The American school of sociological jurisprudence, led by Roscoe Pound, was strongly influenced by the pragmatist teachings of William James and John Dewey. Sociological jurisprudence preached the necessary and proximate relationship, or symbiosis, between law and society—that is to

say, the notion that the criteria for evaluating and appraising the positive law at any time must include (1) the extent to which that positive law in fact reflects the complex of interests pressed in society at that time, and (2) the extent to which the positive law has changed in measure with that society. The values to which a sophisticated legal system must give effect include both the interest in a reasonable stability of settled legal expectations and the interest in mobility and change in law, lest the positive law, if too unimaginatively and rigidly applied, should act as a brake on future social development.

The legal realists charged that in attempting to balance these two opposing principles the common law systems, certainly until the 1930s, over-emphasized the interest in stability and predictability of legal relationships and forgot the maxim that "the life of the law has not been logic, but experience" (see, for example, the writings of Karl Llewellyn and Jerome Frank). The theories of most legal realists emphasized the law-making role of appellate judges. The recent emphasis on the more dynamic elements in law (see the work of Myres McDougal, Harold Lasswell, and others) represents, in addition, a return to an earlier common law philosophy, a philosophy which had, after all, so successfully transformed the common law from crude and unrefined custom, in the closed medieval society, into an instrument of social control amply suited to the resolution of conflicts and tensions in modern complex industrial civilization.

III

CODE LAW SYSTEMS

The term "code-law systems" is usually employed, as a legal term of art, with two different, if related, meanings. First, "code" refers to the reduction of the laws customarily observed by a particular people to a more or less permanent, organized, and written form through a comprehensive piece of legislation or *codification*. Strictly speaking, a "code" may denote a constitution or similar public-law enactment of fundamental laws; but more usually the term is limited to compilations of the private law (contracts, torts, property, agency, marriage, matrimonial property, and related matters), although many countries also have codifications of their criminal law, criminal procedure, civil procedure, and commercial law. It is in the general sense of there being a collection in a single, comprehensive statute of particular national laws on one or more main subjects that the code-law systems are normally opposed to uncoded, or common-law, systems. In the latter systems, in general, the private law at least remains an uncoded body of what were originally custom-derived rules or principles that purport to be reflected in the judgments of the highest national courts and in piecemeal statutes that may be passed *ad hoc* to correct or extend those judicial decisions.

In a second and more popular sense, the term "code-law systems" denotes the body of continental European civil law, which, as represented principally in the two major acts of codification of modern times, the French civil code (or Code Napoléon) of 1804 and the German civil code (Bürgerliches Gesetzbuch, or B.G.B.) of 1900, has spread throughout the world. The German civil

code of 1900 had a decisive influence on the drafting and adoption of the present Japanese civil code and on the precommunist Chinese code. The Code Napoléon has been widely copied or borrowed from in the codifications of the Middle East, former French Africa, and Latin America generally.

It is in this particular sense of referring to the substantive civil-law content of the two great western European acts of codification that the term "code-law systems" is normally distinguished from the common law of the English-speaking countries. The common law of England was carried by process of conquest, occupation, or settlement, to the original American states and to the British colonies overseas. With some modifications based on deference to existing local, customary law, in the case of certain countries having an indigenous, predominantly non-English or non-European population, the common law has remained in these countries even after British political power has formally and practically disappeared. Thus the common law is today the basic private law of Great Britain, the Commonwealth countries, and the United States. The term "common law" applies both where the common law has itself been codified—as is the case in most of the English-speaking countries in regard to commercial law and criminal law—and even where the law was originally Romanist (as in South Africa and Ceylon) and, while still formally uncoded, was transformed by successive decisions of the Privy Council in London into a semblance of the common law, case law system of precedents. An act of codification is always something of a revolutionary step in the sense that it represents a certain intellectual break with the past. Although all the codes purport to be merely a restatement of the old, pre-existing law, most of the great codifying commissions have used the opportunity to make innovations and changes in the old law; and the act of codification itself, in the sense that it involves reducing a large and hitherto unorganized mass of materials to comprehensive form, necessarily involves a certain clarification and streamlining of the existing law.

The great codifying projects have usually coincided with eras of great political or social change or upheaval, probably because in such periods it may be easier to obtain that minimum degree of consensus among the decision-making elite necessary to force such projects through to completion. It may be only in such periods that the conflicting pressures for stability and change can be satisfactorily reconciled to the point of reducing the

laws to a single, comprehensive enactment. The French civil code was adopted in the wake of years of revolutionary turmoil in France and was one of the first projects of the Emperor Napoleon, who personally guided it through to completion, to the point of sometimes presiding himself at the sessions of the codifying commission. In Germany the codification movement only really got under way and received official blessing after the achievement of German political union, in federal form, in 1871; and codification was then looked upon as an instrument for assisting and furthering the spirit of national unity.

In the case of Quebec, the civil code of 1866 was adopted at the time of the pending political incorporation of French-speaking Roman Catholic Lower Canada into a Canadian confederation in which French Canadians would be heavily outnumbered by English-speaking Protestants: the codification of French Canada's civil law was viewed as a defensive measure to protect the distinctive social values and institutions of Quebec (for example, the family law, with its emphasis on the family unit with paternal control, the absence of any divorce, and the institution of the joint matrimonial property system) against the encroachment, after confederation, of an alien common law that was viewed as incorporating Anglo-Saxon Protestant values.

The modern Japanese and Chinese civil codes, with their large German civil law influences and derivations, were adopted as part of a deliberate policy of modernization or "Westernization" of basic social institutions, with a view to speeding large-scale industrialization and development.

The Soviet Russian civil code of 1922 was adopted at a time when governmental pressures in the Soviet Union were all for stability, clarity, and certainty in law, after the disastrously chaotic experiences in the era of free law finding from 1917 to 1921. During that period, the tsarist codes and laws had been largely swept away and Soviet judges and administrators were often bound by a no more sure and reliable criterion for decision than their own "spirit of revolutionary consciousness." The year 1922 also marked the introduction in the Soviet Union of the New Economic Policy, with an official relaxation of controls on economic activity and a new encouragement of entrepreneurial business activity and of foreign trade and investment in the country. It was, therefore, argued that a fixed and definite civil code—which manifestly, in its structure and organization and in a great deal of its substantive principles, too,

did not depart too much from the main continental European civil-law stream—would be an invaluable asset in promoting a more liberal Soviet official image, both at home and abroad.

Individual national codes differ widely, depending principally upon whether their makers have looked to the French or to the German civil code for their main intellectual inspiration. The Code Napoléon is direct, lucid, and often sparkling in structure and in language, reflecting perhaps both the inherently graceful qualities of the French language and the personality and techniques of its original drafting commission, whose members, essentially practicing lawyers, under some prodding from the Emperor Napoleon produced their final code in a matter of several months. The B.G.B., by contrast, is heavy, pedantic, and profuse, both in language and in drafting, reflecting in measure the essentially professorial and bureaucratic character of its main drafters and the years of research, public debate, and criticism that preceded its final adoption; for although the actual project for codification was put under way in 1874, with the appointment of the members of the codifying commission, it was not until 1896 that the final draft was completed and approved, to take effect from 1900. The Emperor Napoleon had said that his aim was to have the code so simple and convenient in its arrangement that the French peasant, reading it in its single, slim, pocket-book form by candlelight, would be able to know his legal rights; and so successful has the code been, from the viewpoint of legal writing, that Stendhal is said to have read a few pages of it each day to improve his literary style. The German code, by contrast, remains essentially a legal technician's code, without any particular claims to literary elegance or refinement of style.

This reference to a distinctive national psychology or personality—or *Volksgeist*, as Savigny called it—and its relationship to individual acts of national codification calls attention to the question of whether there are any particular periods in a nation's history that are especially ripe for codification, and perhaps it also poses the even more basic question of why some countries have achieved codes and others have not. In 1814, in reaction against the various French invasions and military occupations of the revolutionary and Napoleonic eras, Anton Thibaut and the German nationalist movement urged the immediate codification of German laws. Savigny, who opposed these pressures, argued that since a code existed primarily as a restatement or concretization of a

nation's law it would act as a brake on national development if any nation should seek to codify its laws before it had reached its full political, social, and economic maturity. Savigny added a nationalistic argument to his injunction against any "premature" codification. He stated that, given the condition of German law at the opening of the nineteenth century, when only the loose, diffuse, and prolix Prussian code of 1794—an original project of Frederick the Great acting under the impulse of French rationalism—was available as a strictly Germanic model, any German act of codification, unless it were to be a reproduction in terms of the Code Napoléon, which had been carried into the Rhineland and other parts of Germany by Napoleon's armies, would require legal talents and resources beyond the then existing intellectual capacities of the German university law faculties.

It was far better, in Savigny's view, to keep the existing patchwork quilt of German law. In the Rhineland states, for example, the Code Napoléon would be retained; in Prussia and the areas under its control, the code of 1794; in the other states, the uncoded common law, or "received Roman law." The absorption of this uncoded law into Germany had taken place over the course of the fourteenth, fifteenth, and sixteenth centuries. In the process of that absorption and in the subsequent intensive study in the university law schools, it was progressively refined and restated. There is a particular irony in Savigny's argument against codification by appeal to German nationalistic traditions, since the received Roman law, which dominated so much of Germany at the opening of the nineteenth century, became ultra-Roman in content and character. Even the Code Napoléon, for example, while drawing heavily on the Roman law of southern France (or the *pays de droit écrit*), was still greatly influenced as to its substantive principles by the Germanic customary law of the northern provinces of France (or *pays de coutumes*).

A good part of the dynamics of a codification movement certainly comes from the spirit of rationalism. There have been powerful codification movements in both Great Britain and the United States. Bentham and his disciples, as part of their general law-reform movement in the early nineteenth century, launched a codifying project designed, in Bentham's own words, to render the law "cognoscible" to the layman. But the movement, except for some sustained influence in certain specialized areas of law, especially the criminal law and commercial law, and in the

British colonies overseas, had largely petered out by the middle and late nineteenth century, probably because of the tenacious resistance of the vested professional interests of the judiciary and the practicing bar. The intellectual thoughtways of these special skill groups were attuned to that pragmatic, problem-by-problem development of legal principles inherent in the case-law system, and they were firmly opposed to any a priori postulation of principles through an act of codification. Since university teaching of law in England was very weak and largely unorganized until well into the nineteenth century, the practicing profession's influence was dominant in legal education through the Inns of Court, and this acted as a further intellectual barrier to codification.

In the United States the codification movement had its impact, represented in the great Field-Carter debate of the mid-nineteenth century; but the influence of codification has been very slow and, outside the commercial sphere, limited in area of impact. On the other hand, some factors have been very conducive to uniformity in the development of American private law, notwithstanding the existence of fifty formally separate and autonomous state jurisdictions. Especially important are the Restatements of American Law and the influence of the prestigious "national" law schools of the pattern of Yale and Harvard, which purport to teach a truly national, as distinct from a particularist or local law.

Once they have been drafted, there is a certain tendency for codes to become invested with a great deal of the seeming permanence, rigidity, and immutability of constitutions or similar fundamental laws. This particular truth, which had been observed by Savigny, seemed to be amply vindicated by the detailed history of the interpretation and application of the Code Napoléon during the nineteenth century. In France a highly conservative judiciary, aided by a strict and literal "grammatical" construction or exegesis of the text of the code, insisted on confining its practical application to a highly individualistic laissez-faire philosophy, at a time when France as a whole, speaking in social and political terms, had experienced a full-scale industrial revolution and had largely accepted collectivist or social democratic ideas. Yet, by the close of the nineteenth century the judiciary, aided by the work of a brilliant group of text writers and commentators, had begun systematically to reinterpret the Code Napoléon to take account of the new climate of an advanced industrial civilization, in which the code must operate. The operational tools for this trans-

formation of the code were the new techniques of teleological interpretation (or interpretation in terms of social purposes), themselves products of Génys's call (1889) for free scientific research in law (*la libre recherche scientifique*). These developments in French code law in action parallel and anticipate the later realist and sociological emphases in North American jurisprudence.

Codes, like constitutions, if they are to be viable, must change with the society in which they operate; and this preferred relationship, or symbiosis, between law and society is assisted by the use of broad general formulas in drafting them. When the German Social Democrats were disposed to challenge the draft B.G.B. because of its alleged liberal, individualistic bias, the great jurist Rudolf Stammier was able to assure them that the lapidarian quality of the code's general provisions would make it continually adjustable to the community's own acceptance of social democratic ideas. The very generality of a code's key provisions—like the "due process" clauses in the fifth and fourteenth amendments to the United States constitution—enables new content to be poured into the old formulas. Thus the process of interpretation can serve to effect change and innovation in the law while avoiding the apparently radical step of direct legislative amendment.

SOCIALIST LEGAL SYSTEMS—SOVIET LAW

Despite its stormy history, the Soviet legal system has acquired a definite character and gives evidence of being permanently established. Many of its features derive from prerevolutionary Russian origins and are therefore similar to those of other legal systems (especially the German and French), from which Russia borrowed in the nineteenth century. Other features, however, are peculiarly Soviet, reflecting the needs of a one-party state, a planned economy, and a social order directed toward a communist morality.

Development

In the first two decades after the Communist seizure of power, in 1917, Soviet legal institutions had to contend with the official Marxist-Leninist theory that law (like the state) is essentially a capitalist institution destined to wither away (literally, "die out") once socialism is established. This theory derived from the premise that the apparatus of political authority (the state) and the formal procedures and general rules enforced by such apparatus (law) are essentially instruments of domination by the ruling class. They would have to be retained during the period of proletarian dictatorship but would not be needed in the future classless society, which would regulate itself, like a family or a kinship society, by customary standards, by morality and common sense, and by a recognition of the identity of individual and social interests.

In the period of War Communism, 1917–1921, the new Soviet regime made strenuous efforts to eliminate the legal institutions of the prerevolutionary period and to usher in the new classless society as rapidly as possible. The formal political and legal institutions that were introduced were quite primitive in character and were thought to be very temporary. By 1921, however, the entire economy was at a standstill, and Lenin introduced the New Economic Policy (NEP); private trade was restored, foreign firms were invited to do business on the basis of "concessions," and the peasants were encouraged to sell the produce of their private holdings in the open market. The

restoration of a certain degree of capitalism was thought to require also a restoration of law, and Lenin therefore sent his jurists to the prerevolutionary Russian codes, as well as to western European legal systems, to copy their provisions and adapt them to the new Soviet conditions.

In the 1920s there were promulgated codes of criminal law, criminal procedure, civil law, civil procedure, land law, labor law, and family law. These codes, as interpreted and developed by the judiciary, the bar, the Procuracy, the Ministry of Justice, and legal scholars, gave the Soviet Union a system of law comparable in its techniques and main outlines to those of Western countries. The system was hedged about, however, with provisions designed to prevent its being used contrary to the interests of the proletarian dictatorship.

Thus, article 1 of the Civil Code stated that the rights declared in the code should be protected by law "except in instances when they are exercised in contradiction to their social-economic purpose." Similarly, the Criminal Code, rejecting the "bourgeois" principle of *nullum crimen sine lege*, provided that an act not made punishable by a specific article of the code may, if it is socially dangerous, be punished under articles relating to analogous acts (the doctrine of analogy).

Other features of the law of the NEP that reflected a "proletarian" or "Leninist" orientation included severe limitations upon rights of private ownership, civil liability for causing personal injury regardless of the absence of fault on the part of the defendant, an administrative procedure for divorce by unilateral repudiation, and heavy penalties for "counterrevolutionary" acts or utterances. In addition, the legal system as a whole was rendered somewhat precarious by the theory that it was only part of a transition toward a socialist society in which law would die out.

With the end of the NEP in 1928, the introduction of the first Five-Year Plan, and the collectivization of agriculture, there came a return to the nihilistic and apocalyptic spirit of the earlier period of War Communism. Now, however, a more positive content was given to the notion of the dying out of state and law. These were to be replaced, it was declared, by the plan. The legal institutions of the NEP, although not formally abolished, now became in many respects obsolete. Communist party directives and police terror replaced law in many areas of economic and social life, and Stalin, in that period, built his personal machine for governing.

The spirit of Soviet law in the early 1930s was reflected particularly in the writings of E. B. Pashukanis, the leading jurist of that period, who in his

"General Theory of Law and Marxism" (1927) had expounded the view that law in its very nature is based on the concept of reciprocal exchange of goods and hence is essentially a product of a market economy. In the early 1930s Pashukanis foresaw the imminent disappearance of law and argued that such law as continued to exist in the period of construction of the planned economy should have maximum political elasticity. "The utmost dynamic force is essential," he wrote in 1930. "Revolutionary legality is for us a problem which is ninety-nine per cent political" (*Soviet Legal Philosophy* 1951, pp. 279-280).

In the mid-1930s, however, there was once again a reaction against excessive dynamism. Stalin, in his "Report on the Draft Constitution," 1936, called for "stability of laws." With the adoption of the constitution in December 1936, socialism was declared to have been achieved; class antagonisms were said no longer to exist within the Soviet Union; but at the same time the new socialist era was said to require the strictest legality together with the strongest possible state power. The dying out of state and law was now postponed until the final stage of communism, after the end of "capitalist encirclement"—that is, when the whole world would be communist.

To this postponement Stalin added the "dialectical" doctrine that in order to pave the way for its own abolition the state must in the meanwhile become stronger and stronger. Thus the increase of terror against internal enemies—called agents of foreign imperialism—was given a theoretical justification, while at the same time the stabilization of the legal system could be promoted in those areas of social and economic life where terror was not considered necessary.

The dual system of law and terror that Stalin established in the mid-1930s is well symbolized by the fact that Pashukanis' nihilistic theories of law were denounced and he himself was shot as a counterrevolutionary. He was replaced as dean of the Soviet legal profession by Andrei Ia. Vyshinskii, who laid down the new party line about law in a series of articles and in a book on Soviet public law (1938). While defending party supremacy and the use of force against "enemies of the people," Vyshinskii attacked Pashukanis and other Soviet jurists for their attempt to reduce law to economics or to politics. He asserted that law has an "active, creative role" to play in the Soviet planned economy and that the reduction of law to politics would signify the ignoring of those tasks that stand before law, such as the tasks of legal protection of personal, property, family, testamentary, and other rights and interests (1938).

Under Vyshinskii's aegis the whole vocabulary of "rights," "duties," "legality," "contract," "ownership," "inheritance," "fault," "independence of the judiciary," "right to counsel," "burden of proof," and the like was carried over from the NEP period and rebaptized as "socialist both in form and in content." Moreover, the escape clauses of the NEP codes, such as article 1 of the Civil Code and the doctrine of analogy in criminal law, were greatly restricted in their application. In criminal law the element of personal guilt was emphasized as an essential element of crime. Liability for personal injury was now to be based on fault rather than on mere causation. A judicial procedure for divorce was introduced. Freedom of testation was increased, and the maximum 90 per cent inheritance tax was eliminated and replaced by a maximum 10 per cent notarial fee.

At the same time, "counterrevolutionaries" and "enemies of the people" were generally dealt with in secret administrative trials by the Special Board of the Ministry of Internal Affairs (MVD) or in a special secret procedure in the military courts. (The great purge trials of 1936-1938 were an exception to this rule.) Indeed, Vyshinskii developed theories to justify the application of special legal doctrines in political cases—for example, the theory that confessions have special evidentiary force in cases of counterrevolutionary crimes, since no person would confess to such a crime unless he were actually guilty!

The restoration of law as a positive feature of Soviet socialism was part of a general stabilization of social relations that occurred in the mid-1930s. It was related to the restoration of historical traditions, the re-emphasis of family stability, and the stress on Soviet patriotism, as well as to the recognition of the need for personal material incentives and for greater regularity and calculability in the administration of the economy. In the sphere of constitutional law, however, including choice of leaders, the legislative process, and civil liberties, "socialist legality" was largely a facade for Stalin's personal despotism.

After Stalin's death, in 1953, his successors denounced his "violations of socialist legality" and restricted very substantially the use of terror. They abolished the Special Board of the MVD and the special procedures in military courts for counterrevolutionary crimes. Hundreds of thousands of persons who had been convicted of counterrevolutionary crimes were released from labor camps and rehabilitated. Confessions were deprived of special evidentiary value, and the burden of proof was placed squarely on the prosecution in all criminal cases. The doctrine of analogy was eliminated from

criminal law. New laws provided for the publication of all statutes and executive decrees having "general significance." There was also a slight narrowing of the law on counterrevolutionary crimes (renamed "state crimes"), although it remained a crime to defame the Soviet political and social system or even to possess written materials of such defamatory nature for the purpose of weakening Soviet authority. The regime in the labor camps (renamed labor colonies) was substantially reformed.

Even apart from political crimes, Soviet law underwent substantial liberalization in the years after Stalin's death. There was a re-examination of virtually every branch of law and a weeding out of most of the harshest features. Between 1958 and 1962 "Fundamental Principles" were enacted by the U.S.S.R. Supreme Soviet in the fields of criminal law, criminal procedure, civil law, civil procedure, and judicial administration. On the basis of these Fundamental Principles the various Soviet republics have begun to enact new codes in these fields. Draft "fundamental principles" of labor law were published in 1959 and were still under discussion in 1965, with new Fundamental Principles of family law in preparation as of that date. The new basic legislation has effected not only a general liberalization of the pre-existing law but also a significant systematization and rationalization.

Characteristics

Among the distinguishing features of the Soviet legal system is the institution of the Procuracy, which was established by Lenin in 1922 on the model of the old Russian Procuracy established by Peter the Great. The procurator-general of the U.S.S.R. and his subordinates at all levels have the function not only of indicting and prosecuting criminals but also of supervising legality generally. "General supervision" includes "protesting" administrative abuses to higher administrative authorities, as well as "protesting" erroneous judicial decisions to higher courts. Any citizen may complain about an abuse of his rights to the Procuracy, which is required to investigate and reply to the complaint and in proper instances to "protest" it. Thus, the Procuracy exercises a "watchdog" function, without having administrative powers of its own (apart from the power to indict for crime). It is a legal institution peculiarly adapted to a political system in which there is a high degree of central administrative regulation.

A second characteristic Soviet legal institution is the system of administrative adjudication of contract disputes between state economic enter-

prises and organizations. So-called *Arbitrazh* tribunals hear such disputes and resolve them on the basis of contract law, administrative regulations, and state economic plans. Where plans require enterprises to enter into contracts for supply of goods and the enterprises cannot agree on the terms, *Arbitrazh* tribunals will hold hearings and resolve the dispute. Most of the several hundred thousand cases decided annually by *Arbitrazh* involve, however, not these "pre-contract" disputes, but suits for specific performance or for damages for breach of contract.

A third distinguishing feature of the Soviet legal system is its heavy stress on the educational role of law. Both substantive and procedural law, in virtually all fields, is oriented toward the guidance, training, and disciplining of Soviet citizens to be loyal, responsible, and devoted to the aims of the society as formulated by the Communist party. A specific manifestation of this "parental" philosophy is the law of official crimes, which makes administrative and managerial personnel of state organizations criminally liable for intentional malperformance or negligent performance of their official duties.

The emphasis on the educational role of law is connected with the theory of the dying out of state and law once communism is achieved. In 1961 the achievement of the first stage of communism was promised within twenty years. At the same time the Stalinist theory that the state must get stronger and stronger in order to create the conditions for its demise was rejected. The 1961 Communist party program declared that the period of proletarian dictatorship was over and that Soviet society would take immediate (although very gradual) steps to replace the coercive machinery of the state by the persuasive, voluntary processes of popular social action. In accord with this theory, various paralegal bodies have been established—notably, informal "comrades' courts" in factories and apartment houses, which mete out reprimands and light fines for minor offenses, as well as "people's patrols" (*druzhiny*), which act as volunteer auxiliary police. In addition, people who lead an "antisocial, parasitic way of life" and "live on unearned income" are tried by collectives of workers or by the courts in a special administrative procedure and are subject to "resettlement" for two to five years in places where they must take socially useful jobs.

The adoption of these "antiparasite" laws in the major republics in 1961 coincided with a general increase in harsh penalties for serious crimes. Thus, in 1961 the death penalty was introduced for large-scale economic crimes, counterfeiting,

and illegal transactions in foreign currency. In 1962 repeated bribery of officials, rape committed by a group, and attempted homicide of a policeman or volunteer auxiliary policeman (*druzhinnik*) were added to the list of capital offenses. (Prior to 1961, only certain political crimes—treason, espionage, banditry, wrecking, terrorist acts—and murder committed under aggravating circumstances were subject to the death penalty in time of peace, and in 1958 the maximum period of confinement had been reduced from 25 to 15 years.)

Thus, as of the early 1960s there was a certain ambivalence in the Soviet legal system. On the one hand, many of Vyshinskii's theories justifying the use of terror were denounced, and socialist legality was proclaimed to extend to all spheres of Soviet life. On the other hand, the dualism of law and terror was replaced by a dualism of law and informal social pressure, and law itself, although applied with greater objectivity than ever before in Soviet history, reflected increased harshness in some areas and increased leniency in others. Soviet jurists rejected Vyshinskii's definition of law as a coercive instrument of state domination (embodying, Vyshinskii added, the will of the people); yet they were unable to find a new definition that corresponded to Marxist-Leninist theory, to the new conditions of Soviet life, and to the aspirations toward a communist society in which social influence and persuasion would replace formal rule and command.

BIBLIOGRAPHY

The major "classics" of Soviet legal theory in the period prior to Stalin's death have been translated in part by Hugh W. Babb in *Soviet Legal Philosophy* 1951. No one has emerged to replace Vyslunskii as dean of Soviet jurisprudence (1938). Among those scholars, formerly associated with Vyshinskii, who have been in the forefront of the reform movement since 1955 are M. S. Strogovitch, S. A. Golunskii, A. A. Piontkovskii, and S. N. Bratus. Of the younger jurists who first came to prominence in the middle 1950s, O. S. Ioffe is perhaps the most outstanding. An extensive bibliography of Soviet legal writings may be found in Hazard & Shapiro 1962.

LEGISLATION

- I. NATURE AND FUNCTIONS
- II. LEGISLATURES
- III. LEGISLATIVE BEHAVIOR

Benjamin Akzin
Ralph K. Huitt
John C. Wahlke

I

NATURE AND FUNCTIONS

The term "legislation," in its narrowest modern usage, denotes the enactment of rules of law by specialized State agencies endowed with high authority and fairly representative of the general population; the term also denotes the rules that result from this process. In a wider sense, legislation includes, in addition, rules of general application enacted by executive, by subordinate administrative, by regional, and by local authorities. Rules of this kind are also known as secondary, or subordinate, or delegated legislation. At times, the term is used in a still broader meaning, in relation to rules stemming from other than State authorities (e.g., church or international legislation).

Legislation, thus understood, presupposes a fair degree of political and legal differentiation. It requires, first, a well-understood distinction between general norms intended to govern human conduct in an indefinite number of future instances and individual norms or commands intended to apply in a specific instance or in a strictly limited num-

ber of specific instances only. It requires, second, a well-established distinction between institutions authorized to issue general norms and those not authorized to do so; and more particularly, the setting up of a *central* agency equipped with this authority—the legislature in the proper sense of the word. It requires, third, a fair degree of consensus that norms thus enacted rank above most other legal rules found in the society. In more primitive legal systems, where such differentiation has not taken place and where society is largely regulated by rules to which metaphysical or customary origin is ascribed and which are regarded as beyond deliberate change by man-made institutions, one can hardly speak of legislation. And in those modern societies where differentiation of functions disappears in the plenitude of power wielded by an individual or by a small collective group—notably in some dictatorships—the concept of legislation as a distinct function suffers a serious setback.

Development of the concept

The term "legislation" derives from the Latin *lex*. The *lex*, once Roman law emerged from its primitive stage, was a distinct kind of legal rule of overriding authority and mainly of general application, expressly enacted by the people or on their behalf by some highly placed institutions (monarch, senate), singly or in combination. The same institutions were also regarded as entitled to modify or abrogate a *lex* once passed. It was therefore a term narrower than *ius*—the sum total of rules presumed to govern human conduct, whatever their authority, scope, or procedure of formation. It was, more precisely, an especially authoritative rule of the *ius civile* in the original meaning of the expression (i.e., the law which the State-organized society, *civitas*, provided for the regulation of conduct within itself), of what is called today "positive law" (i.e., imposed by the State) and of the *ius scriptum* (written, or enacted, law). Within this area of written positive law, the *lex* is a specific rule attributed to the highest law-making authority, which thus becomes the legislative authority *par excellence*. By definition, any other rule of positive law is viewed as subject to the *lex*, and if it acquires a status equal to a *lex*, it is said, in the language of Justinian's *Institutes* (I, II, 4), to "have the force of a *lex*" (*legis habet vigorem*).

Whether "nonpositive" law, which claims derivation from religion, from nature, from ethics, from reason, or from various ideological assumptions, is also subject to State-made legislative rules or,

on the contrary, represents a "higher law" that states may not transgress, has remained a point of controversy in theory and still more in practice, ever since antiquity. Even custom and judge-made law were often regarded as immune from legislative interference, and not until the seventeenth century in England was the supremacy of legislation over the common law definitely acknowledged.

Several terms in various European languages—*loi*, *legge*, *ley*, *Gesetz*, *zakon*, and in English *a law* (as distinct from *the law*), but more precisely *statute*, *Act of Parliament*, *Act of Congress*—were coined to conform more or less to the historically developed meaning of *lex*. Upon closer observation, the criterion of generality appears in all of these to be rather incidental. The Romans had already noted that there are personal laws not intended to establish binding standards for future conduct (*leges . . . personales quae nec ad exemplum trahuntur*). Indeed, individual and special laws continue to form a considerable part of the legislative output in most civilized states. The decisive criterion for identifying legislation as a process and laws as the product of the process is increasingly the formal criterion of the identity of the enacting agency. In a curious reversal of roles, instead of legislation being explained as the activity which aims at the enactment of laws, we tend today to hold as laws those rules which are arrived at by the process of legislation.

Neither in antiquity nor in later times did specialists, let alone general usage, adhere strictly to the above meanings of the terms. In Rome *lex* was often used instead of *ius* to denote a whole area of jural regulation (e.g., *lex mancipi*, *lex commissoria*); and even another part of Justinian's codification (*Digest* I, III, 1) defines *lex* in a far broader manner than does his *Institutes*. *Lex* apparently had already become a highly popular expression, as overworked and used as indiscriminately as *law* in the English language today. In some other modern languages, the distinctiveness of the term is better preserved because, like Latin, they have a second term at their disposal (*loi-droit*, *legge-diritto*, *Gesetz-Recht*, *zakon-pravo*); but there, too, confusion is not unknown.

With the emergence of the Roman emperor and his appointees as the center of all governmental functions, a special legislative agency and its specific product, the *lex*, though maintained in theory, lost all practical importance. Different rules now stemmed largely from the same sources and from the same motivations; it hardly seems worthwhile, therefore, to pay much attention to formal differences between them. The influence of theology on

juristic theory in the centuries after Constantine's conversion to Christianity made the distinction even less meaningful. The three systems of the *ius naturale*, *ius gentium*, and *ius civile*, which the Romans were at such pains to keep distinct, tended to coalesce, the law of the church proper was added to them, and all four claimed ultimate legitimation by the same authority. Both enacted and customary rules of municipal law were occasionally described as *leges*, but so were the asserted principles of *ius gentium* and of *ius naturale*, as well as rules which claimed none but divine authority. Feudalism, too, contributed to this development. A device for maintaining social organization in the face of a weakened central power, it preserved no specific function as that power's sole prerogative but opened all of them, including the enactment of general rules, to the interplay of bilateral feudal relations; agreement and custom tended to rank above enactment in the legal structure. *Lex* and its plural *leges*, though at times used in contradistinction to *consuetudines*, extended beyond the particular rule and embraced a whole body of rules, being used in this sense concurrently with *jus*. *Lex Salica*, *lex Romana*, *lex civilis*, *leges Langobardorum*, and in private international law, *lex fori* and *lex contractus*, became technical expressions in which *lex* stood for *jus*.

From the eleventh century on, the revival of the original concept was stimulated by the universities, where Roman law dominated the jurists' thinking. The strengthening of the State at the expense of feudalism, which followed soon after, again lent reality to the distinction between higher-ranking and lower-ranking rules, and between individual and general ones. The *statutum* was defined as a written, general enactment, and the authority to enact statutes as the *potestas statuendi*. When exercised by the supreme political authority, it became the *potestas legis ferendi*. The *legis lator*, an expression known already in Rome and used there, as was the Greek *nomothetes*, mainly to denote an individual leader endowed with charisma or exceptional wisdom, like Moses or Solon or Lycurgus, appeared in a French source of the fourteenth century in its modern institutionalized meaning.

Further developments were again intimately connected with the gradual differentiation between the functions of various State agencies. As long as different rules emanating from the prince enjoyed similar status in the legal system, there was not much point in drawing formal distinctions between them. No doubt, certain restrictions were considered binding upon the princes of continental Europe, and some acts called in theory for the consent

of representative assemblies. But in actual practice, most of these representative assemblies lost their powers, and the absolute power of the princes became prevalent, sweeping away before its authority all distinctions between basic and subordinate rules. Where, however, the representatives played an active part in the law-making machinery, e.g., in England, the Netherlands, Poland, the Italian and Hanseatic city-republics, and the Swiss cantons, the differentiation between rule-enacting agencies sharpened the differences between the resulting sets of rules. A rule which could be made only with the consent of a representative assembly and had to be modified in the same way was considered higher law than that enacted by mere executive authority. In monarchical countries such as England, the Netherlands, and Poland, this conception was somewhat blurred by the existence of the prince's "own right" or "prerogative"—a rival system of law impenetrable to the powers of the representative body. Nevertheless, there too the rules enacted by consent of representative bodies emerged as rules of higher authority, both in the consciousness of the population and in juristic practice. These were the rules that became increasingly identified as legislation, first in England and then in continental Europe.

In England special authority was early attributed to enactments agreed upon by the king and an assembly, soon to be divided into two houses. Thus arose the Act of Parliament, the first modern legislative act. The identity of the body which, in addition to the king, participated in the enactment; the procedure of this participation; and the social consensus symbolized by it lent special significance to the enactment. The contents of the act were of minor importance. Quite often its scope was general, but even where the same procedure was observed with respect to a measure of limited scope or applicability, the measure still enjoyed the same high degree of authority. Down to the seventeenth century there were many attempts to contest the special status of Acts of Parliament, to attribute a similar status to certain measures enacted on the king's sole authority, and to dispute the authority of Acts of Parliament to deviate from the common law; but by the end of that century the superiority of these acts over both king and common law stood unchallenged.

This concept of legislation, identified by the participation of a representative body in the enacting process and given a pre-eminent position in the State's scale of norms, remained virtually unchanged until the end of the eighteenth century. Both Continental and English philosophers and

jurists adopted it and helped to spread it among the growing literate stratum of the population. A change ensued when the United States, followed by France, inaugurated the era of formal constitutions. These, wherever adopted, have displaced the ordinary laws, enacted through the legislative process, from their theoretical and moral pre-eminence in the legal structure, and—to the extent that the supremacy of the Constitution was accompanied by judicial or other sanctions—the displacement was of practical legal significance as well. Otherwise, legislation and its products—the laws, in the narrow meaning of the word—remained in their place, at or near the apex of the legal structure.

Secondary legislation

The stress of modern conditions has resulted in complications connected with (a) the complexities inherent in an industrial society, (b) a closer relationship between executive and legislature, (c) a generalized pattern of self-governing units, (d) the problem of meeting emergencies, and (e) the growth of modern dictatorships.

The complexities of modern society, combined with the increased social welfare purposes of the modern State, call for a vastly increased intervention by public authorities in areas of social relations which in former times had been regarded as lying outside the authorities' field of interest. Both administrative convenience and an increased sensitivity to the "rule of law" and the principle of equal treatment militate against exclusive reliance on *ad hoc* decisions, demanding instead regulation by general rules. But the very number of the general rules required, the complexity of their subject matter, and the specialized knowledge needed for their formulation make it difficult for the legislature to solve the problems incidental to their enactment. Willy-nilly, legislatures acquiesce nowadays to the enactment by administrative agencies of general rules, which but a few decades ago would have been regarded as reserved to legislation proper. [See DELEGATION OF POWERS.]

This trend was greatly assisted by a major change that has taken place in most countries of the world in the relations between legislatures and the top layers of the executive arm. No longer do these institutions represent two different principles of legitimacy and two different social groupings, often with opposing interests and credos and generally suspicious of each other's objectives, one centering on the prince, the nobility and the top bureaucracy; the other, on a broader group not intimately associated with the day-to-day conduct

of public affairs. Nowadays the government, the top layer of the bureaucracy, and the legislature all trace their authority to the same source—the “people” (whatever the measure of reality or fiction behind this attribution)—and to a large extent share or reflect identical social interests. In those countries where some variety of the parliamentary regime prevails (i.e., one in which the heads of the executive are permanently answerable to the legislature and may be dismissed at the latter’s discretion), it is the practice to place the direction of executive affairs in the hands of a group of persons who not only are for the most part members of the legislature enjoying the confidence of a majority of their fellow members, but are actually the leaders of that majority. In the circumstances, despite disagreements and mutual jealousies which still persist between executive and legislature, their conflicts can in no way be compared in intensity to those which marked the relations between the two in the days when they represented opposing principles of government and divergent social forces. In the modern State a large degree of basic unity of purpose and outlook between the legislature and the executive leadership replaces the fundamental lack of confidence which formerly existed between them.

This new situation explains why parliaments have largely abdicated their policy-making function to governments, whose lead they now tend to accept, but it explains more particularly why the former parliamentary reluctance to let executive agencies enact far-reaching general norms has considerably weakened. Many a statute is no more than an *enabling statute* authorizing the president, the cabinet, the minister, the subordinate executive department or officer to issue general rules within a very wide range of discretion. At times, special statutory provisions are aimed at exempting such rules and the decisions based on them from effective judicial review. Other general rules are issued by the executive without express authorization by statute, in the exercise of its powers under the Constitution, or of its police powers, or under the theory of the implied powers of government; and the legislature, as long as it does not disagree with the government on major questions of composition or policy, does not generally object. Action which in the former days of struggle between prince and parliament would have been resisted by the latter as usurpation of power, is now accepted as normal, inevitable, or even desirable, in the interest of good government.

This state of affairs is not without its influence on the judiciary and on academic jurisprudence:

courts have accepted it, and so have universities. In theory as well as in practice, the border line between legislation and regulations has become blurred, and regulations with more or less general contents are increasingly referred to as “secondary” or “subsidiary” or “delegated” legislation. Statutes passed by a parliamentary body are no longer the only form of legislation; they are distinguished merely by being “primary legislation.” And the body itself is no longer the sole legislator; it is but the “primary legislator.” In Britain this development has been most pronounced and, despite occasional protests from the traditionalist legal profession, is growing stronger. Other countries influenced by English law follow suit, and so do countries of the civil law tradition. In the United States, “delegation of legislative powers” is still rejected in principle, and the country’s courts attempt to enforce this prohibition. But the factors that made for the practice elsewhere are active in the United States as well, and though the character of “legislation” is denied them, far-reaching general norms without much statutory guidance are becoming the rule.

Another kind of “secondary legislation,” widespread in the modern world, is that indulged in by local authorities when making general rules within the scope of their jurisdiction. This trend goes back to medieval towns, many of which had representative institutions at a time when states were still governed autocratically, a circumstance which facilitated the conception of a difference between rules enacted by representative authorities and those made by executive authorities alone. Indeed, the very term “statute” was largely used to denote acts of self-governing local or regional authorities. But while, in premodern times, the jurisdiction of local authorities was often based on special arrangements and charters, it now conforms to a general State-wide pattern. In this pattern, the local authority consists of a predominantly elected representative body and of administrative personnel headed by an individual (mayor) or a small committee of officeholders with departmental responsibilities. Within this structure, the bifurcation into “higher” rules issued by the larger representative body and the acts of the “executive,” bound by those rules, resembles the legislative-executive relationship within the State and justifies the designation by analogy of the “higher” local body as legislature and its output of general rules as legislation. In relation to the State, though, the rule-enacting activity in question is, of course, limited by State agencies and is subject to a variety of controls both before and after enactment. By

no means can this activity pretend to "high" status within the total legal structure, however valued the principle of local self-government may be in current political thinking. At most, these acts too could be considered a kind of "secondary legislation" in the British sense. The special designation of "bylaws" points both to the analogy these rules bear to legislation and to the difference between them. [See LOCAL GOVERNMENT.]

The discussion of near-legislative activities by local authorities applies equally to representative regional authorities. The size of a regional entity, the scope of its authority, and the over-all status it enjoys in the politico-legal scheme of things do not theoretically affect the situation as described. In the United States this holds true of the school district as well as of the county, in England of the parish as well as of the county, in France of the *arrondissement* as well as of the *département* and the *région*.

It even holds true, to some extent, of regional entities in a federation which by courtesy, tradition, or formal enactment are accorded the dignity of statehood, whatever their precise designation (*states* in the United States, Australia, India, and Mexico; *republics* in the Soviet Union and Yugoslavia; *provinces* in Canada; *Länder* in Austria and the German Federal Republic; *cantons* in Switzerland). The scope of jurisdiction of these units is usually much wider, and within that scope they are much freer or altogether free from central controls; their status is anchored in the constitution and is often entrenched against interference by the federal legislature; and tradition or the letter of the constitution may describe them as "sovereign." Nevertheless, theirs too is an authority derived from a body politic larger than their own. Often there is the added limitation that in case of conflict, a federal statute will prevail over the product of the "member-state" legislation, thus relegating the latter to a clearly subordinate plane.

A further phenomenon which complicates the legislative picture is the emergency regulation. The ordinary regulation (variously known also as executive order, *décret*, *Verordnung*) and any action undertaken pursuant to it are characterized by being quite often an execution of a specific statute and, in any case, subject to statutory and constitutional provisions; this, as well as the sanction of judicial control of all regulatory activities, is the principal concomitant of the *rule of law*. However, genuine emergency conditions are apt to arise—mainly in connection with wars, internal disorders, severe economic crises, and major disasters—which make it imperative to allow for measures

that would be free from the time-consuming procedures accompanying modern legislation and yet might deviate from statutory and perhaps even from constitutional provisions. The proclamation by the executive of martial law, of a state of emergency, or of a state of siege has variously served in the past to justify such deviation from the normal rule of law pattern and is still occasionally resorted to, but whether or not accompanied by such proclamation, the emergency regulation (or emergency order) has become the main form of such exercise of executive powers in the twentieth century. Where war was concerned, Great Britain (until 1920) and the United States have found it possible to postpone the enactment of a suitable legal framework of emergency powers until the emergency has actually arisen and to do so by means of *ad hoc* legislation. Thus the British Defence of the Realm Act and the American Emergency Powers Act were passed in these countries in connection with the two world wars. In many other countries, however, where there are good grounds to fear a more instantaneous emergency, provision for such powers has been made ahead of time as part of the country's permanent structure, and even Great Britain now has the permanent Emergency Powers Act. The abuse of emergency powers that occurred in central Europe, notably in Germany, in the 1930s has made countries more cautious and has caused them to place emergency powers under increased parliamentary and judicial control. Nevertheless, even regulations passed under this conception of emergency powers approach legislation in the narrow sense of the word: they are not strictly bound by pre-existing statutory law; they enjoy a position of pre-eminence roughly approximating that of statutes; and they are held in check but little by judicial review. It is even more difficult than in the case of ordinary "secondary legislation" to ensure that the essential distinction between emergency regulations and parliamentary legislation be properly observed. [See also CRISIS GOVERNMENT.]

The previously noted complications arise even where the individuals and groups in control of the executive are willing to abide by the limitations placed on their powers and do not seek to overthrow the rule of law. Where this condition does not apply, the difficulties noted are aggravated, and the observer encounters a wholesale and deliberate trespassing by those who control the executive on what would be regarded as the normal domain of the legislature. Like those earlier regimes where power was highly concentrated, modern dictatorships, whether ideologically moti-

vated or merely ambition-driven, whether totalitarian in their policies or fairly liberal, tend to obliterate the distinction between legislation and other procedures of law making. Representative legislative institutions are either abolished, or reduced in authority, or transformed into mere instruments whose composition and deliberations are wholly managed by the wielders of executive power. In either case the intrinsic importance of legislation and the distinction between it and other rules of law are diminished. [See TOTALITARIANISM.]

Structure of legislatures

The foregoing observations have shown that the body regarded specifically as the legislature bases its claim to higher legitimation on its being more fully representative than other public authorities. The actual mode of determining that body's composition, as well as the relative weight of the circles and interests thought worthy of representation, vary in accordance with the views prevailing at the time in the given society generally and among those who occupy the centers of power especially. A common characteristic of all properly differentiated legislatures is that they are *collective* bodies—an elementary device which makes fuller representativeness more likely and an excessive concentration of power less likely than would be possible in the case of a one-man legislature. *Appointment*, whether for a given period, for life, or even to a hereditary seat, was often practiced as a suitable mode of composing the legislature along with or instead of *election*, and this mode is still found in the mid-twentieth century in a number of "upper chambers," e.g., in Afghanistan, Canada, Ethiopia, Jordan, Luxembourg, the United Kingdom, and the Republic of South Africa.

Historically, the division of legislatures into two houses or chambers is a survival from the strongly estate-conscious medieval society, when deliberative bodies with partly legislative functions were organized by estates or groups of kindred estates. With the weakening of the estate as the prime integrating group and the strengthening of the direct links between the individual and the State, the "lower" chamber, based on some system of fairly wide and, most recently, near-universal adult suffrage, became the principal vehicle of mass representation, while the "upper" chamber was used to add an element of conservatism, moderation, or stability to the legislature. Conditions of eligibility and of voting were formulated more strictly in upper chamber elections, indirect elections were resorted to in the hope that they would screen out radical elements and make for a higher

level of expertness, and appointment was often practiced. All these methods could ensure weighted representation to social groups and interests favored by the regime. In federations, the device of the upper house is generally used to secure special representation of the federated entities, sometimes on the basis of equality irrespective of population numbers, thus affording the smaller autonomous units additional protection against encroachment by the larger ones. With the continuous growth of the idea that election by a larger proportion of the population furnishes the elected body a fuller measure of legitimate authority, the political importance and the formal attributes of upper houses gradually declined, except in some federal unions where they are regarded as the guardians of the federal principle. Several countries have dispensed with upper houses altogether, and the tendency seems to be spreading. In 1963, the list of countries with unicameral legislatures embraced a number of Latin American states, all unitary states with communist regimes, most of the new states in Africa and Asia, and Cyprus, Denmark, Finland, Greece, Israel, Lebanon, New Zealand, and Norway.

The shift from legislation

Legislation has constituted the principal business of parliamentary bodies almost from the beginning, a circumstance which so impressed political philosophers of the seventeenth and eighteenth centuries, especially Locke and Montesquieu, that they saw the creation of a specialized representative agency as principal participant in the legislative process to be a prominent characteristic of a well-ordered State. With modifications, this conception, an intrinsic part of the separation-of-powers doctrine, became the predominant practice, and representative parliaments became associated in the popular mind with the legislative power as such. In fact, however, this identity is by no means complete. In this article, some of the reasons have been set out which made parliaments lose much of their decisive role in the legislative process. In addition, parliaments in a number of countries occasionally share the legislative function with binding or advisory plebiscitary procedures (Australia, Austria, Denmark, France, Germany during the Weimar Republic, Italy, New Zealand, Norway, Switzerland, and—quite often—member states in federations) or with heads of State who may grant or withhold consent to a pending bill (United States, most other presidential republics, and constitutional monarchies of the nonparliamentary type). Nor can the representative char-

acter of parliaments always stand scrutiny. The not-quite-representative character of many an upper house has already been commented upon. Elections in which only part of the adult population was given the franchise and individual votes were given unequal weight were quite common until 1918. Since then, both practices have become less frequent, except in the form of assigning larger representation to rural than to urban constituencies—a practice still widespread. [See APPORTIONMENT.]

A newer problem is posed by parliamentary bodies in countries with communist, "popular-democratic," "guided-democratic," *caudillo*-type, and fascist regimes. There, parliaments are encountered which, though elected on an extremely broad suffrage basis and sometimes with an unusually large participation of voters, have their election process so encumbered with formal and factual restrictions on free discussion of issues and free choice of candidates, in an atmosphere so dominated by governmental and reigning-party pressure, that their representative character is doubtful in the extreme. The weaker a parliament's claim to be widely representative, the less foundation there is for its claim to have a preponderant part in legislation.

But even aside from these particular weaknesses, the significance of parliaments as legislative agencies has generally decreased. The connection between this development, the complexities involved in modern law making, and the greater unity of outlook between modern legislatures and executives, has been set out earlier. Even in the United States, where legislative activity proper is carried out more fully and more jealously by Congress and by the state legislatures than in most other countries, the national or state administrations initiate an ever-increasing portion of the more important bills. The American legislature is still in a position to deny clearance to a legislative measure desired by the administration, but less and less frequent are the cases in which, overriding a president's or a governor's veto, a legislature is able to enact a measure to which the administration objects. [See PRESIDENTIAL GOVERNMENT.] In other countries, to the extent to which parliaments are the expression of the voters' choice rather than of the governing group's pressure, legislation conforms to an even greater extent to the executive's desires. The executive's subordination to parliament is expressed mainly in the former's composition, so constituted as to ensure that the latter will confidently accept its guidance. Where parliamentary regimes are con-

cerned, it is also expressed in formal votes denoting continuance or discontinuance of this confidence. But as long as a government enjoys a parliament's confidence, executive guidance of legislative business is accepted as a matter of course. [See PARLIAMENTARY GOVERNMENT.]

Nonetheless, parliaments, other than single-party ones, continue to exercise considerable influence on the specific contents of legislation. Bills introduced on the initiative of the government quite often undergo radical change as a result of discussion on the floor and in the committees of the legislature, and of public debate. Furthermore, bills are often introduced by the government or on its behalf as a result of opinions expressed in the legislature and of similar bills proposed by the opposition.

In matters of budgetary and finance legislation, special procedures have grown to hinder parliaments from seeking to please the voters by simultaneously advocating increased expenditures and decreased taxes—a double treatment necessary at times but dangerous when used indiscriminately. In several countries such devices were adopted as limiting parliament's opportunity to propose expenditures over and above those suggested by the government, making such increases conditional upon simultaneous provision for added revenues, or providing for a lengthened legislative procedure (such as an authorization and an appropriation act in the United States; the financial resolution in Great Britain). Long-term financial provisions such as the British Consolidated Fund, multiyear plans involving financing and enacted in advance, and authorization of economic activities controlled by the government and carried on through the intermediary of public corporations have further reduced the significance of the annual budgets handled by parliaments as part of their legislative routine. [See BUDGETING.]

Not only has the part of parliaments in the over-all legislative picture become smaller. Legislation has also become a less important, though not necessarily less time-consuming, part of parliamentary business. Its place has been taken largely by two other functions: the day-to-day control of governmental operation and the formalized, highly resonant expression of the grievances and aspirations of groups within the population. Speeches on the floor and in committee, interventions by members with appropriate ministers and their officials, questions or "interpellations," "points of order" and motions of different kinds ascending in intensity to the (British) motion of censure and the (continental European) motion of nonconfi-

dence serve these various purposes. In the United States, some of these forms are not used, but their place is taken no less effectively by the formalized procedure of open hearings in legislative committees and the informal contact which members of the legislatures maintain with the press and other mass media so as to mobilize the latter in the service of causes to be supported or fought. Legislatures and their members thus become highly sensitive parts of the machinery of government, attuned to currents of popular opinion, capable of broadcasting their own moods to the population, and constantly pressing the resulting views on the administration.

If modern parliaments are still regarded largely as the legislative agencies par excellence and legislation is still represented as their principal business, this is, to some extent, an echo from the past, perhaps a reminder of a weapon parliaments hold in reserve to be used against the executive in some future contingency but hardly a fair description of the actual state of affairs. Those "legislatures" which have been deprived of the dynamic role of daily controllers and gadflies of the administration because of the utter subservience of their membership to the executive, and which have been reduced largely to legislative activity—again in an atmosphere of such subservience—lead but a shadowy existence. For obvious reasons, opposition groups and members in parliaments—wherever genuine opposition is allowed—are much freer from executive dominance than are groups and members that support the government of the day, both in their legislative and in their gadfly activities, and they appear by and large as the more dynamic part of the legislature. Only where party discipline is lax do members of the group pledged to support the government make themselves strongly felt in the conduct of parliamentary affairs. This is the case to a very marked extent in the United States and to some extent in Italy; such was the case in France during the Third and Fourth republics, and with respect to a few individualistic members of other parliaments (e.g., in Britain, Winston Churchill and Leopold Amery among the Conservatives; Stafford Cripps and Aneurin Bevan among Labour party members). [See PARTIES, POLITICAL.]

Legislative techniques

Typical of modern legislation is the elaborate procedure intended to avoid drafting errors and hasty decisions. Both the guiding ideas and the actual text of the original proposal may be suggested by an individual member of the legislature, by a group of members, by a partisan body, by an

outside group primarily interested in the issue, by a government agency, or by experts to whom the task has been entrusted by one of the foregoing. Where formal introduction of bills by the government or a government minister is allowed, the role of the individual legislator in initiating legislation has been on the decrease, and so have his chances to have his bills considered on their merits or adopted. Legislative counsel, legislative reference services, and experts attached to specific legislative committees are growing in importance as media for assembling information, drafting documents, or otherwise assisting members and committees of the legislature. With the formal introduction of a text for consideration as a proposed piece of legislation, the text becomes a *bill*. In most legislatures, either members or the government (in the United States only members) are authorized to introduce bills.

Though subject to serious modification in detail, the legislative process commonly involves four stages. Upon formal introduction in parliament, the bill is either automatically turned over for consideration to an appropriate committee or first briefly discussed in plenary session (first reading) with a view to dismissal or to retention for further consideration. In Britain and some countries that closely follow British procedure, the next stage (second reading) takes the form of a debate in plenary session, which, in turn, is followed by consideration in committee (usually a smaller body chosen *ad hoc* or generally entrusted with matters of that kind, but in Britain often the "Committee of the Whole House"—i.e., the entire membership of the chamber proceeding in a less formal manner). In most other countries, consideration in a smaller committee comes first; and the second reading in the plenary session, with opportunity for detailed discussion and vote on individual sections of the bill, takes place only after it has been "reported out" by the committee or (in the United States) after the committee has been "discharged" from further consideration of it. (The discharge procedure is a remedy against undue dilatoriness on the part of the committee or the committee chairman.) Representatives of the government are usually heard by the committee, and in most countries other interested parties may also be heard (in the United States predominantly in open hearings, in other countries mainly behind closed doors). During the committee stage, especially when proceedings are held behind closed doors and do not involve the prestige of individual members, of parties, and of the government in the same measure as in public session, considerable changes are

often introduced into the original text in response both to argument and to pressure. The last stage (third reading) usually involves a brief debate and, in most countries, concludes with a vote on the bill as a whole, although under British procedure the debate is more extensive and opportunity is given to decide on various amendments that have arisen out of committee proceedings.

Ordinarily, intervals of several days, weeks, or months separate these stages. Indeed, such intervals are regarded as desirable in order to permit thorough deliberation and to enable public reaction to make itself felt. But in emergencies legislatures resort to a "suspension of the rules," limiting debate, shortening the accepted intervals between stages, dispensing with committee consideration, and even passing the entire measure in the course of a single day.

Other decisions taken by legislatures are not to be confused with legislation proper. These include elections; votes of confidence, nonconfidence, and censure; votes of impeachment; expressions of approval or disapproval of administrative measures that require such action; procedural decisions of various kinds (including the determination of rules of procedure, or standing orders, under which the legislature operates); and especially declaratory resolutions of different kinds which may be morally and politically significant but have no binding force in strict law. In the United States Congress, it is important to distinguish between "joint resolutions," which are tantamount in their effect to statutes, and "concurrent resolutions," which in themselves have no legal effects. Where legislative agencies also have constitution-making and constitution-amending functions, procedures governing them should be distinguished from those involved in "ordinary" legislation.

Voting procedures differ greatly among the legislatures of the world and, depending upon circumstances, even in the same legislature. The vote may be taken by an informal estimate of the strength of the voiced (*viva voce*) approval and disapproval, by a "show of hands" or a "rising vote" estimated or actually counted, or by more formal counting ("division" in the British Parliament), by roll-call votes registered by name, or even by secret ballot. A simple majority of those voting, with abstentions not taken into account, is usually decisive, and most legislatures require either a low proportion of members to be present at deliberations or votes (*quorum*) or no *quorum* at all. The British House of Commons requires a *quorum* of only 40 members (out of 630 in 1963); the *quorum* requirements of both houses of the United

States Congress of a majority of all members are among the strictest. There are, however, legislative and other decisions which require, to become effective, an absolute or an even higher majority of all members voting, of members present, or of the total membership.

Participation of other bodies in the formal legislative process is secondary in the modern State. Formal consultation of economic councils of various kinds takes place in some countries. Under some newer constitutions, an appropriate judicial or semijudicial body may be requested for its opinion if the constitutionality of the measure is doubtful (in Iran the Council of Ulema, i.e., religious dignitaries, passes on the religious orthodoxy of the measure), and, if necessary, the bill is returned to the legislature. More widespread is the opportunity given to the head of state to withhold his consent to the bill, thereby either preventing its passage into law (absolute veto) or requiring its consideration anew by the legislature (suspensive veto).

Except in very special circumstances, publicity is a mark of modern legislative procedure. This publicity serves to enable public opinion and that of interested groups to make their weight felt before the final decision is taken, as well as to rally the public around the decision's results. The bill, after having been given the assent of all those whose participation is required, is certified, proclaimed (promulgated), and published, thus becoming a law, a statute.

Interpretation and codification of statutes

In most cases, a statute is restricted to a single subject matter, though this may be quite involved, present many aspects, and require subdivision into several sections or articles. As a rule, the adoption of a statute does not invalidate previous statutes, save insofar as they are expressly invalidated. But where a provision of an earlier statute is inconsistent with the provision of a later statute, the later rule should be applied (*lex posterior derogat priori*), unless the earlier rule is a special and the later a general one, in which case the special rule will prevail (*lex specialis derogat generali*). These and other principles of statutory interpretation are generally left to the courts, which follow certain traditional criteria and their own precedents; where statutes themselves contain rules of interpretation, these are to be followed, of course, but in no case are executive agencies to prescribe rules for the interpretation of statutes in states where the rule of law or the *principe de la légalité* prevails. [See JUDICIAL PROCESS.]

Where partial modification of an existing statute is desired, this is done mainly by an *amending* statute. When this has been done a number of times, or when provisions relating to a given subject matter are dispersed over several statutes (and perhaps over statutes, secondary legislation, and various forms of customary law), a patchwork pattern ensues which makes it difficult to grasp the exact requirements of the law. In the interest of clarification, *consolidated* statutes may then be adopted by the legislature or an up-to-date revision of the statutory material, to be done by experts, authorized by it. When the consolidation of the legal material is done in a particularly systematic and comprehensive manner and purports to regulate fully a very broad sector of social relations, the process is known as *codification* and the resulting product as a *code*. Codification may contain re-statement of pre-existing statutory, customary, and judge-made law in diverse proportions, but also newly formulated rules that differ materially from the law previously in force. Several Oriental, Latin American, and European countries have adopted, virtually unchanged, codes that were previously enacted elsewhere, the most frequent models being the French, German, Italian, and Swiss codes. Such wholesale reception of foreign codes represents a variant of the well-known phenomenon of the reception of foreign law in general.

In its continental European meaning, a code, upon coming into force, is meant to displace all pre-existing law relating to the subject, thus rendering unnecessary inquiry into older sources and precedents, and simplifying access to the law. But in the United States pre-existing law, especially rules derived from the common law and from equity, continue to be regarded as in force, unless specifically conflicting with or expressly repealed by the code. In time, even consolidated and revised statutes as well as codes cease to be up to date: social changes and political aspirations result in partial amendments of the enacted material, and so do technical deficiencies in the original text as revealed in the course of its application. Furthermore, the best-planned and most detailed code or comprehensive statute is overgrown in time by judicial interpretation, even if—as in the case of countries outside of the common law sphere—its interpretation in the light of precode material is discouraged.

The above difference between English-speaking countries and others in regard to codification is related to the different attitudes which legal practitioners and scholars traditionally assume toward the relative places of enacted law and of custom-

ary law authoritatively formulated by a succession of judicial decisions. In civil law countries, legal thought considers law primarily the product of general enactments made by the legislators; custom is but one of the factors which the legislators may take into account; judicial decisions, however important in applying the law to concrete situations, are of merely interstitial significance in classifying, specifying, and sometimes stretching (by analogy, for instance) the general principles of the enactment to cover unforeseen combinations of circumstances—all of this under the guise of interpretation. In common law countries, law is primarily thought of as the body of rules evolved from a succession of judicial decisions on the basis of real or alleged custom, whereas legislation comes in interstitially, to fill the lacunae of the judge-made law or to adjust it to changing demands of society. The formal supremacy of the legislative rule is but reluctantly recognized in the English-speaking world, and wherever possible its significance is reduced by the tendency to interpret the enacted rule in the light of the common law. The difference is further accentuated by the tendency in civil law countries to interpret the enacted rule broadly, so as to bring under its sway as many concrete situations as possible, whereas common law countries tend to interpret the enacted rule narrowly and to continue applying judge-made law outside that narrow area. Basically, the common law attitude reflects the belief that the legislator is inherently a political agent interested in furthering his interests at the expense of true law, somehow related to "natural" law, of which the judge is the guardian, whereas civil law thinking has resigned itself to the acceptance of the legislator as the foremost exponent of the law. [See LEGAL SYSTEMS.]

Legislation and natural law

The foregoing section brings us back to the question of the relation of legislation, as the outstanding instance of a positive, i.e., State-imposed, law, to norms of human conduct which claim validity independently of State action. Where the role of legislator is entrusted to an elected assembly on a broad basis or to direct popular vote, the element of consensus enters the picture, and it is society as a whole that is assumed to impose the law on individual members and groups; still, there is a deliberate act of imposing a rule of conduct which previously could claim no validity. The question arises, in what relation the legislated rule, and positive law generally, stands to *natural law* or morality, that vague but intensely felt body of principles which in human consciousness divides the

just from the *unjust*. In this confrontation, positive law enjoys great advantages: its contents are far more ascertainable, its formulatores are tangible and certain, its sanction is secured by an organized and generally efficient machinery—all unlike the rules of natural law, the precise contents of which are doubtful, the originators and formulatores of which are diffuse in the extreme, the sanctions of which are indefinite and uncertain. [See JUSTICE; NATURAL LAW.]

And yet, for all their weaknesses, natural law concepts—closely intertwined as they are with social *mores*, with rationalized interests and desires, with theological postulates, with individual conscience, and with the ensuing pattern of ethics accepted in society—exercise a permanent influence on positive law in general and on legislation in particular. Enacted rules of law are quite often a reflection of those natural law concepts which prevail at the time. And when positive law appears to one group or another to deviate from natural law, to be *unjust*, it is in the name of natural law, of justice, that changes in positive law are advocated and brought about more often than in the name of any other principle. This applies to partial changes in positive law, which can be accomplished in the forms provided for by the positive law itself, i.e., through the ordinary channels of new or amending legislation, of relementation, of judicial interpretation, and of constitutional amendments. But it applies no less to such wholesale changes of the existing positive legal structure as are accomplished in disregard, even in violation, of these channels, i.e., to *revolutions*. Most revolutions which have a widely acknowledged ideological basis claim to be methods of adjusting the positive law to the true natural law as seen by the revolutionaries.

II

LEGISLATURES

If legislation may be defined as making new rules of general applicability for the future, it should be evident that most, if not all, agencies of government legislate. The judge was probably the first public official to "discover" law, while the legislature, as a self-conscious lawmaking body, is a relatively late creation. The pressures of change induced by the industrial, technological, and scientific revolutions have made even the legislature inadequate, requiring it to lay down broad policy directives and delegate to administrative agencies the power to make actual rules.

If the legislature has no monopoly on legislation, it does at least have a distinct character of its own. Generally it is composed of one or two relatively large bodies of people who, technically at least, are peers. Their authority customarily is derived from some scheme of representation, most often the population living in a delimited geographical area, although there may be some other basis, such as class, or function performed in the system. Because all members are on the same footing and issues are decided by a majority vote, members tend to be or to become generalists, whatever their previous vocation. Except in some upper

houses based on class, members are politicians forced to face the recurrent hazards of the ballot box. These facts are important: they shape the institutional life of the legislature and the attitudes of its members, just as the bureaucracy and the judiciary are shaped institutionally by their own methods of recruitment and advancement and by the materials and methods of decision making on which they must rely.

Legislative structure

The structure of a legislature obviously affects its decision making, although structure is not necessarily the most important influence. There are essentially two models of legislative structure, the parliamentary and the congressional-presidential (referred to hereafter as the "congressional").

The parliamentary model. The crucial element in the parliamentary model is that the executive is selected by the legislature from among its own members. Presumably, then, the executive is responsible to the legislature. This responsibility may be enforced if the executive is allowed to stand only so long as it has the support of the legislature. The executive may in turn have the power to force the dissolution of the house to which it is responsible, thus requiring a new election. It should be obvious that this kind of responsibility is difficult to maintain toward more than one house. In England, where cabinet government emerged, the powers of the House of Lords withered away or were taken away by the House of Commons, as logically they should have been, until convention would not allow a lord to be prime minister (though he might still sit in the cabinet). There are systems, nevertheless, in which some responsibility falls to a second house, as it did in the French Third Republic and still does in some other systems, with predictable difficulties.

Most national legislatures in continental Europe are relatively recent creations or fairly complete overhauls of feudal institutions. In France, for instance, the States-General lay dormant for two centuries during the reigns of divine right monarchs; the National Assembly was a creature of revolution. The only legislature to survive to the present, adapting its procedures and distribution of powers without changing ancient forms, is the English Parliament. When William of Normandy conquered England in 1066, he imposed Norman feudal institutions, including the Curia Regis, a court of nobles who attended and advised him, and the Curia Regis Magnae, a great council that met usually three times a year to give counsel and present petitions. The permanent bureaucracy emerged

from the former, while the seeds of Parliament took root in the latter. Knights first came to the Great Council in 1213, and virtually all elements were represented, after a fashion, in the Model Parliament of Edward I in 1295. The knights, burgesses, and lesser clergy, who represented the communities, met separately from the barons—who were summoned by name—and came in time to be the House of Commons.

It would be pleasant to relate that the members of Commons set about asserting themselves and followed a rational sequence of development to a system of responsible cabinet government—pleasant but not true. Actually, Commons frequently gave away its own tools, and the cabinet developed as a leadership group through necessity, because George I neglected his job. What has emerged nevertheless is a prototype of parliamentary government. The crown reigns but does not rule. The House of Lords sits and talks without power to bother anybody very much. In Commons the government is supreme, initiating legislation, controlling debate, and determining outcomes with the support of its disciplined majority, even when its margin of numerical superiority is quite thin. The notion that the House of Commons will overthrow a government that has lost its confidence is now a fiction. So, apparently, is the description of the prime minister as "first among equals"; a rather weak prime minister, Harold Macmillan, demonstrated that he could shuffle the membership of his cabinet without interference. It is also true, of course, that party leadership in England must consider the sentiments of its parliamentary members and of the country at large, as it probably must in any system and certainly must in a democratic one.

The government nevertheless can be responsible to the electorate because it is in fact in power: controlling the majority party. Its dominance is safeguarded by procedures that deny to the individual member an opportunity to build a personal following that might support him against his party's leadership, and the electorate demonstrates its understanding of the system by retiring the occasional rebel who tries. [See PARLIAMENTARY GOVERNMENT.]

Needless to say, there may be no end of variations on the parliamentary model. In Norway and the Netherlands and in the French Fifth Republic, ministers are prohibited from being members of parliament. They may have been members, they may run again when they are not ministers, but so long as they are in the government, they may be physically in the chamber but may not vote.

Structural differences may have less profound

impact, however, than those induced by other variables in the system. Among the most important of these is the character of the party system. When more than two or three parties elect members to parliament and none has a majority, the coalition cabinet that, perforce, must be formed is likely to lack the stability and poise of a leadership confident of support. In the French Third Republic, where multiple parties could play musical chairs with cabinet seats without having to face a general election, governments fell with boring regularity. The fact that successive cabinets had little actual change of personnel was a consolation to the politicians but did little to increase the prestige of the system. In Germany under the Weimar Republic more than thirty parties reduced the regime to such impotence that the minority National Socialist party easily took power.

The problems faced by a multiparty parliament are enormously enlarged when one or more parties are antidemocratic in ideology and, thus, are determined to bring an end to the democratic game. Hemmed in at both ends of the political spectrum, the democratic parties are forced to mute legitimate differences if the system itself is to stand. Parliamentary government faced this problem in the French Third Republic, as it has in Italy since WORLD WAR II [see PARTIES, POLITICAL, *article on PARTY SYSTEMS*].

The congressional model. The daily operations of the U.S. Congress show a strong influence of British forms and procedure. For example, a speaker presides over the House of Representatives. The constitutional stipulation that revenue bills must originate in the lower house reflects hard British experience, as do the privileges and immunities which members take for granted. But such resemblances are superficial; the constitution fashioned a structure of power unlike the British one, and the forces of American life have strengthened and extended the differences. For example, the American speaker is as partisan as the British speaker is neutral.

The makers of the American constitution followed Locke and Montesquieu in attributing a separation of powers to the British system. More important, their colonial experience encompassed a more or less representative lower house pitted against the executive—the king's representative. Thus, they wrote into the constitution a prohibition against any person's serving simultaneously in both executive and legislative branches. This did not quite accomplish a separation of powers—the constitution provided for a certain commingling of powers, and in practice there has been even more.

Institutions, however, were separated with clean finality. When the Founding Fathers then gave the president and members of both houses fixed but different terms of office, they established conditions making continuous bargaining and compromise an imperative of the system.

British members of Parliament look to the bureaucracy for information, because its ministers are their own men; the same is not true for members of Congress. Congress recognized early that if it were to maintain its independence of, and a semblance of equality with, the executive, it must develop its own research tools. The answer was a system of standing committees, each, in time, coming to have a fairly clear subject-matter jurisdiction, which made it a little legislature within its own sphere of competence. Woodrow Wilson's observation at the end of the nineteenth century that "congressional government is committee government" is still true and seems likely to remain so, barring really fundamental changes in Congressional procedures. Each bill that becomes law must pass the committee test in each house; it may be the subject of hearings, debate, and amendment, or it may die without consideration. If it goes to the floor of either house, it will be promoted there by committee leaders, who also sit in conference with their counterparts of the other body of Congress, to compromise differences written into the bill by the respective houses. Committee chairmen, who gain their eminence through seniority on their committees and retain it so long as they are members, are thus powerful men indeed. Party leaders negotiate with them in a relationship that has more than a superficial resemblance to that of a medieval king and his feudal barons.

Power is further fragmented in Congress by the separation of the legislative and appropriations processes. The expenditure of public funds must first be authorized by legislation considered by the appropriate subject-matter committee in each house. No money can be spent, however, until there has been an appropriation, which is considered not by the legislative committees but by the two appropriations committees. Inasmuch as they may reduce the amount requested or deny funds altogether, they (and their subcommittees) exercise power and enjoy prestige not rivaled by many of the legislative committees.

Power vested in committee chairmen might still be harnessed to party purposes (the chairmen might sit on a party policy committee, for instance, and advance its program in their respective committees) if it were not for the localism of Ameri-

can politics. The constitution requires members of Congress to be residents of the states they represent, and in nearly all cases representatives reside in their districts. The major parties are not truly national; they are federations of state and local parties, held together by the exigencies of presidential politics, unable to help or hurt members of Congress very much. The individual member's constituency therefore is usually paramount; it can end his political life or furnish him a secure base independent of national party leadership. His policy preferences therefore tend to be an amalgam of interests; he may vote with a majority of his party on most issues because there is no conflict but reserve the right to proceed independently when he chooses. Thus, there are very few straight party-line votes in either house, and the president's floor leaders must learn to put together majorities however they can. Interest groups are in the thick of every fight, knowing full well that each contest is in a sense a new one [see PRESIDENTIAL GOVERNMENT].

Problems for research

Legislative-executive relations. The relationship of the legislature and the executive is crucial in any political system; yet analysis of it has not gone very deep. In England the House of Commons may harass its own minister through the question hour, but how much control can a minister who spends so much time on the floor exercise over his department? Indeed, how much does the legislature affect the performance of the bureaucracy in any country? In the republics of France the bureaucrats paid little heed to parliamentary charades. In the United States the oversight of administration is supposed to be a primary function of committees, but not much is known about the complex patterns of relationships that actually exist. Some committees apparently exercise no supervision; others participate as virtual partners in the most important decisions. Indeed, there probably is no more richly varied or complicated political relationship anywhere than that between the president and his establishment, on the one hand, and Congress, on the other. The initiative in legislation has passed over to the executive, but members of Congress share in it. Administration, the responsibility of the executive, is subjected to a variety of Congressional pressures, with results that defy measurement.

Answers to questions concerning legislative-executive relations had to wait for research interest to turn in that direction. In the early twentieth century students of the legislature were likely to

devote themselves to formal descriptions of the institution and its procedures or to legal analyses of its powers and its relations with other organs of government. In the United States such writing was often value-laden; scholars could draw up "model" legislatures because they knew what a good legislature was like and what it should do. This willingness to prescribe, which extended to other public institutions as well, was a product of an earlier generation more confident of the efficacy of reform through structural change. And this trend has not by any means disappeared from American academic scholarship.

Legislative decision making. Beginning roughly with the 1930s, however, attention turned more and more to the political forces that shape legislative decisions—pressure groups, parties, constituencies; this research trend was to manifest itself somewhat later in other countries, particularly England. More recently, legislative research has begun to pry into the internal structure and group life of the legislative body and its subsystems.

A popular tool for this more behavioralistic approach was the case study of some slice of legislative life—the passage of a bill, say, or the activity of an interest group. The case study often gave fresh insights and, at its best, hypotheses worth more rigorous investigation. At its worst, it served as a substitute for analysis, piling up sterile recitals of what happened, which had no cumulative value. Other scholars turned to the public act of decision, the recorded vote, which had the virtue of being a quantifiable unit. With various indices (e.g., liberalism-conservatism, party cohesion, party loyalty) attempts were made to measure the relative weight of contending influences on Congressional decisions. These efforts increased in sophistication with the use of scaling, which tested whether a single attitudinal dimension (e.g., liberalism-conservatism) was in fact being tested, and cluster-bloc analysis, which made possible comparison of the votes of every member of the body on a set of issues with those of every other member.

Needless to say, a fatal flaw of the roll call vote is that it does not reveal vast portions of the legislative process. What finally happens on the floor may be simply the ratification of treaties negotiated elsewhere through bitter disputes. Students of this process face an array of fascinating problems—the relations of the leadership with the rank and file; the internal life of subsystems, such as committees, state delegations, friendship groups, and "classes" of legislators who enter the legislature at the same time; the influence of rules and procedures on legislative outcomes; the legislator's

perceptions of himself, other political actors, and the process; the relations of legislators with outsiders in the bureaucracy, press, interest groups, constituency; and many others. A host of impressions are easy to come by; what is necessary is that some patterns of behavior, individual and group, be identified and some hypotheses as to their relationships be formulated.

Whether they tried to answer such questions or merely sought to get the "feel" of the legislature, political scientists by the mid-1950s were going in person to the legislative chambers and offices. The days were past when a gifted scholar like Woodrow Wilson could write a classic on the American Congress from nearby Baltimore without ever having laid eyes on either house in session. In the United States especially, internships liberally financed by foundations provided for participant observation of national and state legislatures. They led in turn to the actual employment of academic scholars in legislative staff jobs. Interviewing became a popular technique. Usually this was unstructured and relatively informal, but, increasingly, highly structured schedules of questions yielding quantifiable results were used with success.

Questions on process shifted their focus to include analysis of the legislative product as well. Were legislative outcomes actually affected differentially by changes in rules and procedures? Relating process to product suggested a different question: Does the legislature go about settling different categories of policy problems in systematically different ways?

Theory construction. As legislative research increased in systematic rigor and sophistication, the troubling question remained: Does it add up to anything? The testing of isolated hypotheses and the posing of problems for further research lead nowhere unless findings can be related to some tenable theory, even one of the "middle range" (to use Robert K. Merton's term). Theoretical endeavors were obstructed, however, by the difficulties posed by the data. On the one hand, roll call votes were so numerous that even a modest study of one Congress could be costly in time and money. To go back even a few congresses, sort out the votes by parties and other significant categories, and relate them to an evaluation of the significance of the votes was quite beyond the resources of research largely performed by individuals. Moreover, except for recorded votes there were few reliable records. Basic information, such as biographical and political data about members and analyses of the meaning of issues, was lacking altogether or hard to uncover. Tentative generalizations therefore lacked

the crucial historical dimension, which could be supplied only by costly cooperative efforts to discover and store essential data and provide for easy retrieval.

Even if those tasks were accomplished and a reasonably useful theoretical model of a legislature constructed, there would still be no certainty that it had analytical value beyond the legislatures in a single system. A legislature is a part of a political system that in turn is a component of a larger social system. No model that ignored these relationships would make much sense. Obviously it matters what tasks the system assigns to the legislature. Again, the history of a people is important; it determines the level of their political sophistication and the kinds of divisions among the people the political process must bridge. Revolutions, civil wars, military defeats, are hard to assimilate. If the United States can see no end, a century later, to the passions stirred by its one civil war, how much of the difficulties of France should be attributed not to its governmental structure but to its tortured past?

Comparative analysis. If it should prove feasible and profitable to study political systems comparatively, can the same be said for political institutions like legislatures? Have developments in different countries been similar enough to suggest that there is an endemic need in a modern political system for such institutions? Do they perform similar enough functions for the system, do they affect the behavior of their members in ways enough alike, to make a comparative study of legislatures worthwhile? The same questions might be asked about parties, interest groups, bureaucracies, and so on; the issue is fundamental. Whatever the answer, research on legislatures has been almost wholly confined to single systems, with only some tentative comparisons of local legislatures within a system.

The role of modern legislatures

How effective is the modern legislature? This question has been asked earnestly and repeatedly in the twentieth century. The answer usually is that it is not very effective, that it has lost much ground to the executive. In the United States the criticism has been continuous and bitter. Ironically, the British Parliament, which is dominated by the executive and exercises little independent judgment compared to Congress, usually is discussed in deferential terms even by its critics. In any case, the common judgment is that the legislature was better suited to an earlier, more leisurely

day and that its appropriate task now is to react to executive initiative.

The question can be answered analytically only by relating the legislature to the political system of which it is a part. What functions does the legislature perform for the system—that is, what does it do that contributes to the adjustment or adaptation of the system, that is necessary to the maintenance of the system? It is self-evident that a legislature passes laws, but what is there about the enactment of legislation that is functional to the system? When the question of function is raised, it becomes apparent that to be a mere debating society is not contemptible if the debate is necessary to political education or stability. Performing routine chores for constituents is not degrading if the chores serve as a vital link between citizens and government. Legislation that does not accomplish its avowed purpose is not necessarily a sign of impotence; it may provide a symbolic victory for interests not strong enough to prevail. The lonely champion of a hopeless cause has not cried out in vain if he is the champion of the hopeless. Some of the legislative functions may be manifest, in the sense that their objective consequences for the system are intended and identified; some are latent, having unintended and unrecognized consequences. Whether manifest or latent, these functions contribute to the stability and maintenance of the system. It may be that there are common functions that all legislatures perform for their respective systems. If so, it seems likely also that there are functions performed by each legislature that are the products of the unique relationship between the particular institution and the system it serves.

III

LEGISLATIVE BEHAVIOR

In its most general connotation, "legislative behavior" refers to the activities of members of any representative body; in its commonest usage, however, it refers to activities of members of public representative bodies constituted by popular election.

Objectives and methods of study

The earliest relevant literature is the work of certain political philosophers prescribing various rules which they thought proper to guide legislators' actions, generally deduced from their conceptions of the proper functions of legislative institutions. Such literature includes Edmund Burke's familiar strictures concerning the desirability of representatives' being "free agents" instead of ambassadors from local interests (1774), numerous principles of behavior deduced by Jeremy Bentham from his conception of political and legislative functions (1817; 1843), and John Stuart Mill's arguments concerning the desirability of having representatives merely accept or reject proposals formulated by other agencies, or of responding to "free-forming" constituencies created by proportional-representation elections (1861).

Much current legislative behavior study is still concerned primarily with the functioning of legislative institutions, but in quite a different way. Instead of deducing norms of behavior from normative assumptions about legislatures' functions, it tends to discover, describe, and explain actually observable patterns of behavior which presumably are relevant to those functions. A. Lawrence Lowell, in the first modern empirical study of legislative behavior (1902), examined party-line voting in the British Parliament, the U.S. Congress, and several American state legislatures and based his work on implicit assumptions about the relationship between party voting and responsible legislative functioning. Julius Turner (1952), in comparing party with constituency factors in congressional voting, was more explicit about this

functional relationship, and David B. Truman (1959) not only explored the patterns of such influences in the U.S. Congress in still greater depth and precision but also sought more explicitly than previous investigators to identify and secure data concerning the legislative functions in question. A number of contemporary investigators, particularly Duncan MacRae, Jr. (1958), have explored overt and latent bases of cleavage and consensus underlying legislative voting, relating these either explicitly or implicitly to decision-making and value-allocating patterns characterizing the over-all legislative process.

The development of the "political behavior approach" influenced legislative behavior study as early and as much as it influenced any branch of political science. In the 1920s Stuart A. Rice (1928) and Herman C. Beyle (1931) had already suggested legislative roll calls as a fertile field of data to be explored by new, quantitative methods of analysis devised by them. The previously mentioned works of Turner and Truman, in fact, relied heavily on the methods of Rice and Beyle, respectively. E. Pendleton Herring's pioneering study of group representation in Congress (1929) and the "noninstitutional," "realistic" process studies stimulated in part by it (e.g., McKean 1938; Schattschneider 1935; Zeller 1937), while not precisely focused on legislators' behavior as such, nevertheless impelled attention to it by questioning the adequacy of purely formal and legal descriptions. The principal concern of these and many later writers, however, is still essentially "institutional," that is to say, related to questions about the structure and functions of the legislature or of the wider set of political institutions. They deal not so much with legislators' behavior as with legislatures' activities, with legislative decisions rather than with legislators' choices. Their dependent variables tend to be process variables (e.g., characteristic ways of handling issues in different legislatures) or "output" variables (e.g., characteristic types of legislation produced under different circumstances). The behavioral indexes of such variables may be the aggregate voting of legislators on relevant roll calls, but the problem treated is that of relating the aggregate behavioral variable to some ecological, demographic, political, or other characteristic of the political or social system rather than explaining variations in behavior among individual legislators.

Of course, legislative decisions are definable only in terms of their component individual actions, so the behavior of individual legislators has in a sense had the theoretical status of "intervening variable"

between social, political, and other determinants of individual behavior (as independent variables) and legislative output and functioning (as dependent variables). But preoccupation with the aggregate of individual actions, the legislative decision, long inhibited scholars even from classifying legislators' behavior in terms of analytic concepts relevant to the explanation of individual behavior. The common practice was to make descriptive classifications in terms of those overt actions—above all the roll call vote—most directly and obviously related to the aggregate legislative decision. Even other categories of behavior which relate almost as clearly and directly to this function as do roll call votes (e.g., initiation or introduction of proposals, floor speeches, and actions in legislative committees) rarely were used to describe legislative behavior systematically.

Instead of inquiring into the antecedents of legislators' behavior, most research proceeded rather uncritically from assumptions about the bases of behavior, which were almost never made explicit. A simple *rationalistic model* pictured the legislator's activity as the outcome of individual means-ends calculations on his part. According to its simplest version, a legislator, knowing what "the public interest" is, acts in an effort to promote it. More complex versions envisage more demanding information-seeking and analytical efforts by him to discover what the "public interest" requires in specific instances and to assess the relative utility of various means of furthering it [see PUBLIC INTEREST]. The *group pressure model*, on the other hand, pictured the legislator acting primarily in response to specific cues or orders from external agencies—constituents, executives, pressure groups, lobbyists, political party agents, friends, relatives, and many others. These pressuring agencies might act out of selfish desire, out of reasoned conviction about the public interest, or other motives. And the legislator's motives for responding to the "pressure" might vary from plain fear to agreement in principle with the pressuring agent. But legislators' actions will in any case be seen as an arithmetic sum of the amounts and directions of the different pressures on them [see POLITICAL GROUP ANALYSIS]. Sometimes, particularly in normatively oriented works, these two models have been treated as the ideal and the perverse extremes of legislative behavior, with the actually observable behavior of "real" legislators in each case presumably lying somewhere between.

The inadequacy of such frameworks for the investigation of individual legislators' behavior was implied by one of the first types of behavioral study,

the tabulation of various social, economic, and political "background characteristics" of the individual legislators. This line of investigation, suggested as early as Lowell's time (Orth 1904), was pursued particularly by Charles S. Hyneman and his students (Hyneman 1940; Hyneman & Lay 1938), who made extensive inquiries into the occupation, political career, legislative tenure, and other characteristics of legislators in a number of American states over considerable time periods. Although, as Hyneman himself explicitly pointed out, there were few hypotheses and no clear theory about the relationship between background characteristics and legislative behavior, the assumption that some relationship did exist was made quite explicit. And it seemed clear to most scholars that this assumption fitted poorly with either rationalistic or group-pressure conceptions.

At the same time, increasing sophistication in more general conceptions of political structures and functions led to increasing awareness of hitherto neglected aspects of legislative behavior. For example, the many, varied "errand-boy" activities performed by legislators in many systems, informal but structured relationships among legislators (friendship, etc.), and numerous other aspects were seen to be as important for understanding the functioning of legislatures as were roll call votes. The importance of attitudinal dimensions of legislative behavior was emphasized by studies which viewed legislators' conceptions of themselves and their legislative jobs as the proximate indicators, if not the determinants, of their behavior (Silverman 1954).

It rapidly became accepted, therefore, that legislative behavior is social behavior in a particular institutional context, not atomistic rational calculation or mechanical reaction to mechanical impulsion or pressure. Increasingly the effort has been to conceptualize and explain legislative behavior more fully, both with respect to the amount and manner of its effect (as an independent variable) on legislative functioning and output and with respect to its relationship (as dependent variable) to other varieties or more general principles of human behavior. Recent studies, for example, have sought to relate the behavior of legislators to the group life of the society and to the role concepts of legislators as individuals (Patterson 1958) and to explain significant aspects of the observed behavior of legislators in terms of role theory (Wahlke et al. 1962), reference-group behavior (Michel 1964), or other social-psychological and psychoanalytical premises (Barber 1965).

Advances have also been made in surmounting

some of the methodological limitations which characterized earlier legislative behavior research. One limitation has been the failure to encompass the universe of public representative bodies. American social scientists, who have been responsible for most of this research, have generally confined their attention to American legislatures. Of the relatively few studies dealing with behavior in non-American legislatures, a disproportionate share are the product of American scholars (e.g., Aydelotte 1963; MacRae 1963). Although studies of behavior in American state legislatures and city councils are increasingly frequent (e.g., Zisk et al. 1965), research in America, as in other countries, has tended to concentrate on the national rather than on local or intermediate levels of government. There have been some important studies of behavior in international or supranational bodies, but they are relatively few (Alker & Russett 1965).

Moreover, despite the example of comparative analysis set by Lowell's pioneering venture, research has more often than not taken the form of case studies. There are numerous important exceptions, but, quantitatively speaking, the literature to date offers primarily studies of single legislatures rather than comparative studies, either of different legislatures or of single legislatures at different points in time. Research has often attempted to explain the historically unique features of particular events, decisions, or policy problems in a particular legislature. As a result, it is relatively difficult to establish generalizations by cumulating findings about legislative behavior even in a particular legislature, despite the qualitative richness of many available studies.

Another methodological limitation has been the tendency to utilize only the most obviously available types of data. Official documents, such as legislative journals and reports of debates, committee reports, newspaper accounts, and similar records provide a seemingly rich mine of data for a number of national legislatures, including the U.S. Congress, the British Parliament, the French National Assembly, and others, as well as for the United Nations General Assembly. Where such data have been readily available, a number of studies have been based on them. But, except for numerous roll call analyses, these studies have been more intuitive than systematic. Rarely have such data been subjected to content analysis or other objective techniques. Roll call analysis, however, has been developed with considerable methodological sophistication, so that various types of scalogram, factor, and other mathematical analyses of roll call data are by now familiar (Anderson et al. 1966).

Another frequently used type of documentary data is the legislative "blue book," or regularly published summary of memberships, legislative assignments, and limited biographical and other related information. A number of social background and recruitment studies have been based at least in part on these (e.g., Finer et al. 1961; Hyneman 1940; Hyneman & Lay 1938; Matthews 1954; 1960).

The most important methodological development in legislative behavior research since the beginnings of roll call analysis has been the use of new sources of data and new methods of gathering them. Systematic interviewing of whole legislative memberships or samples of them is perhaps the most widely used such method (e.g., Wahlke et al. 1962; Barber 1965). But direct observation, systematic surveillance, and participant observation, frequently in combination with systematic interviewing, have also produced some interesting findings (Crane 1959; Patterson 1958). Increasingly sophisticated methods of observing, recording, and analyzing data obtained by these methods promise further fruitful results.

Perhaps the most persuasive sign of methodological maturity in the field of legislative behavior research is the increasing frequency of efforts to combine many types of data, subjected to various types of analysis, in comprehensive assaults on theoretically important problems. Miller and Stokes (1963), for example, have combined survey and other data, utilizing imaginative statistical techniques, to investigate the problem of representation. Bauer, Pool, and Dexter (1963) have explored policy formulation in a broad context, also using a variety of data and techniques. It is fair to say, therefore, that by the middle 1960s legislative behavior had become an identifiable field of research and study, part of the mainstream of empirical political and social research; that scholars in the field were contributing their share of methodological innovations as well as utilizing techniques developed in other fields; and that research was becoming productive of findings relevant to theoretical interests well beyond the historical events and personages of the particular legislatures serving as research sites.

Dimensions of legislative behavior

The most striking characteristic of current legislative behavior research is the number of dimensions of behavior it envisages. Reference was made above to the categories of activity examined in legislative research. One important new category was revealed by the theoretical recognition (or recollection) that legislatures are, after all, political

institutions. As such, legislatures in general are essentially patterns of behavior, and each specific legislature is a particular institutionalized group by virtue of the specific behavioral uniformities exhibited by each legislative generation and passed on from it to the next.

The uniformities which constitute the legislative institution have their roots in the constitutional and statutory definitions of legislative functions and tasks, but they go well beyond the formally prescribed behaviors. "Folkways" or "rules of the game," which include not only direct norms of behavior but also sanctions against violators, have been identified in a number of different representative bodies (Matthews 1960; Wahlke et al. 1962; Kornberg 1964). They prescribe such behavior as respect for fellow members' rights in the legislature and in politics; engaging in debate only when informed on a subject, and then with due restraint; standing ready to compromise rather than holding dogmatically to fixed positions; and so on. They have been shown to serve the functions of promoting cohesion and solidarity of the legislative group, channeling and restraining conflict, expediting the conduct of legislative business, etc. [see RULES OF THE GAME].

These norms enter into legislative behavior as major elements of the legislators' conceptions of the legislative role. They are the behaviors expected of individuals associated with the office or position of legislator, by legislators themselves and by their fellows. Besides "rules of the game" the legislative role includes norms concerning (1) the legitimate purpose of legislative activity (identifying social problems and inventing solutions to them, acting as broker between competing groups and interests, etc.), (2) the representational focus of the legislators' actions (the community collectively served by the whole legislature, the local community or constituency which elected the legislator, etc.), and (3) the style of representational judgment ("independent judgment," orders or advice from party leaders or powerful constituents, etc.). The legislature collectively gets work done because the job of legislator is perceived by all legislators in terms of such categories (even though there may be variation among members' conceptions of them).

Moreover, legislatures tend to develop roles obviously related to legislative task performance, to which the same principles apply. The positions of formal and semiformal leaders (speaker, committee chairmen, party leaders, whips, and so on) have role behaviors associated with them. In most legislatures there are also highly informal specialized roles that play an important part in the legislative

process. One of these is the role of "subject-matter specialist," a status recognized by legislators, who tend to accept the advice or recommendations of such specialists not on the basis of their party affiliation, personal friendship, or political identification, but directly on the basis of their recognized "expertise" as knowledgeable, though nonprofessional, specialists. It has been demonstrated that such "experts" make their influence felt not just within their own party but among members of other parties as well (Wahlke et al. 1962, pp. 193-215).

Certain other relationships among legislators play a part in their legislative behavior even though they may be peripheral or irrelevant to legislative purposes and legislative roles as such. Friendship groups and cliques, for example, have been found to influence voting, debating, and other categories of behavior. Such groups may be based on affective social ties (*ibid.*, pp. 216-235; Patterson 1959), on membership in a common state delegation (Truman 1959), or other nonlegislative social bases. These groups, which are never large (a dozen or more is unusual), tend to form within parties more than across party lines. There is an even stronger tendency for veteran legislator groups to be relatively impervious to newcomer legislators (who, as might therefore be expected, tend to form friendship groups among themselves).

Like social roles in general, legislative roles are conceived in terms of behavior appropriate for an individual in relation to some specific "significant other." In the case of the above-described rules of the game, the legislator's "significant other" comprises all his fellow legislators. But the legislative system (a network somewhat wider than just the legislature itself) includes numerous other classes of "significant others" with whom legislators interact with sufficient regularity to generate other components of the legislator's role. In most legislatures today these classes would include the chief executive and his representatives and aides, administrators, party officials (both within the legislative party leadership and in the broader party organization outside), lobbyists and other pressure-group representatives, and different categories of constituents.

One important dimension of legislative behavior, then, is the number of different categories of behavior which have analytically been found to be subsumed in legislative role concepts and manifested in legislative role behavior, and the amount and type of variation in these respects found empirically to occur between members of a given legislature and between patterns found in different legislatures.

A closely related dimension involves the synthesis of these components by individual legislators and its consequences for collective legislative action. The aggregative and individual behavior approaches intersect at this point. The aggregative approach sees it as a problem of assessing the relative significance of competing determinants of legislative decisions (e.g., parties versus pressure groups versus constituents). The individual approach sees it as a problem of determining which role cues have most salience for various legislators, which role sectors (e.g., expectations vis-à-vis executive agents, political party agents, lobbyists, etc.) will prevail where there may be role incongruity, or what cognitive and affective structure of individual attitudes will operate under what conditions. On this crucial point relatively little is known. With respect to individual legislative behavior, a beginning has been made at detecting, describing, and classifying individual role orientations in various role sectors—e.g., "trustee," "delegate," and "politico" orientations with respect to representational style (Wahlke et al. 1962)—and styles of conceiving and performing the legislative job in more general terms—e.g., "lawmakers," "advertisers," "spectators," and "reluctants" (Barber 1965). From the aggregative viewpoint, a number of assessments have been made of the degree of influence in particular instances of party, constituents, and other factors—e.g., the many investigations of party cohesion in roll call voting, beginning with Lowell's. There are as yet no instruments and measures for accurately determining the relative influence of such factors or the relative salience of different role concepts and their impact on behavior. Equally important is the theoretical need for more precise and comprehensive conceptualization in this area. It is, therefore, impossible to say with assurance why parties (or constituencies, or other agencies or factors) seem to affect legislative behavior enormously in one system but much less so in another, or even to determine the magnitude of such differences with any precision.

A final dimension, which has yet to receive much attention in research, is that of time—the duration of uniformities of behavior for individual legislators, as well as among groups of them, and the patterns and process of change and development over time. Secular trends in aggregate patterns have been shown to exist in many instances (Buchanan 1963; MacRae 1958), but stability in the behavior of individuals whose behavior constitutes the aggregate picture at any given moment has generally had to be assumed (Aydelotte 1963; Truman 1959). There is now some reason to be-

lieve that blocs and coalitions manifest themselves in a much smaller proportion of legislative business than has generally been believed (Riker & Niemi 1962). But the temporal mechanics of legislative behavior, whether in aggregate or individual terms, is another subject requiring considerable study.

Bases of legislative behavior

To account for variations in behavior along the dimensions described above obviously requires consideration of the mechanics and antecedents of individuals' behavior. Interpretation of behavior patterns identified in various cases is difficult without understanding this. For example, party cohesion was long explained in terms of party discipline, in the sense of more or less coercive activities by leaders, whips, and so on. But studies by Epstein (1960) of the British Parliament, by Dahl (1950) and Truman (1959) of Congress, and by others, point to the conclusion that disciplinary activity by party organizations is much less significant in this respect than are individual legislators' sentiments of party identification. The latter phenomenon must be comprehended within the same framework, to begin with, as the party identification of voters in general. Although it seems clear that other factors also enter in, it is by no means clear how or to what extent. Thus, there is conflicting evidence concerning whether American state legislators are more likely to cohere with their party if they are from safe or from competitive districts (Froman 1963; Sorauf 1963), and some evidence that deviation from party positions by CDU members in the West German Bundestag is traceable to the way in which the structure of interest groups in the party influences its nominations for proportional-representation, as against single-member, district seats (Rueckert & Crane 1962).

It does seem clear that legislators acquire basic elements of the legislative role conception as part of their general political socialization, and not from specific socialization into the legislative group, since all members of all legislatures so far examined on this point appear to recognize and conform to legislative expectations remarkably quickly and dependably upon entry into the legislature. It is not clear, however, whether this is because only certain types of persons, who, for reasons that are not yet known, will already have acquired the particular knowledge in question, are recruited for legislative service, or because general political socialization processes equip practically all members of a given culture with relevant norms that remain latent until called rapidly to consciousness by recruitment into the legislature. Socialization and recruitment

studies to date offer little more than descriptive data about the occupational and social origins of legislators and their prelegislative political experience. [See POLITICAL RECRUITMENT AND CAREERS; SOCIALIZATION, article on POLITICAL SOCIALIZATION.]

The factors offered to account for variations in behavior fall into several identifiable classes, despite the paucity of theory and hypotheses about the exact linkages between the variables and the behavior to be explained.

Ecological and demographic characteristics of salient political units or environments of the legislator have long been presumed to affect his behavior. Reference has already been made to party competition in legislative districts as a possible influence on party identification and cohesion. The socioeconomic character of such units has also been considered an important factor of this kind. In American legislative research it has usually been assumed that the urban-rural character of the unit is the important characteristic in this respect, whereas in other systems the presumption has been that it is differences in social class (workers, businessmen, etc.) which are important. [See PARTIES, POLITICAL, article on PARTY UNITS.]

In neither case has it ever been made clear just how these variables are linked to legislative behavior. Social background and recruitment studies of the characteristics of legislators themselves sometimes imply that legislators individually tend to embody the ecological characteristics described. On the other hand, there is considerable evidence that, at least in American legislative bodies, legislators will in various ways reflect ecological and demographic characteristics of their districts, whatever their own individual backgrounds (Crane 1959). In any case, there is very little evidence for a simple deterministic view of the connection between individual socioeconomic background and individual legislative behavior.

From findings like those concerning the relationship between partisanship and party competition, it may well be inferred that structural and situational political variables have a great deal to do with variations of behavior among legislators. The finding in most American legislatures that constituents and constituency interests seem to have primary salience for most legislators similarly points to the importance of such factors. But there is no accepted theory or model of legislative behavior describing the mechanism by which such variables affect the individual legislators. And there is certainly no accepted explanation for the gross difference in such respects between legislatures.

Despite the fears of some early critics of be-

havioral studies of legislatures, it does seem that the unique personality and character of the individual legislator must be taken into account. An early, never replicated study in one American state (McConaughy 1950), for example, strongly suggested the psychological normality or well-adjustedness of legislators as compared with a matched sample of laymen. Barber (1965) has identified some differences of a psychological order among legislators. And Froman (1963) has shown that the unique "individuality" of Congressmen—elements of personality, outlook, style, etc., as well as views on issues and ideological orientations (if any)—leaves detectable traces in their legislative behavior.

The tasks of future legislative behavior research, then, include the elaboration of theories and concepts which will encompass the institution-forming uniformities of behavior within legislatures, the corollary differences and similarities between legislatures in these respects, and the differences in behavior among members within a legislature. Social-psychological frameworks such as role and reference-group theory appear to offer the most promise as guides to these tasks. But it seems clear from work to date that such guides will not by themselves provide answers to the important questions subsumed under the organizing questions—Why do legislators behave as they do, and what difference does it make in the legislative process?

LEGITIMACY

Legitimacy is the foundation of such governmental power as is exercised both with a consciousness on the government's part that it has a right to govern and with some recognition by the governed of that right.

The concept of usurpation as the opposite of legitimacy has accompanied the concept of legitimate government since early medieval times and has helped to clarify it. Usurpers, after seizing power, have often tried to strengthen their positions by giving their governments a legitimate form, and these attempts to clothe a usurping power with legitimacy, whether successful or not, have often revealed what the standards of legitimacy are for a given society or civilization.

Revolutions, unlike usurpation or *coups d'état*, are not necessarily illegitimate. If they succeed they introduce a new principle of legitimacy that supersedes the legitimacy of the former regime. Under such circumstances recognition by the people will often be acquired only as the new government begins governing, and the process of becoming legitimate may include violence and terror. Foreign diplomatic recognition, while not essential, may help internal consolidation and therefore speed acceptance of the new pattern of legitimacy.

Governments, whether following traditional principles of legitimacy or establishing revolutionary ones, may lose their legitimacy by violating these principles. The desire for legitimacy is so deeply rooted in human communities that it is hard to discover any sort of historical government that did not either enjoy widespread authentic recognition of its existence or try to win such recognition. Because it is so universal a phenomenon, however, legitimacy is continuously endangered by the plurality of its patterns and sources. Rivals for power often automatically consider themselves legitimate and their opponents illegitimate. It is therefore difficult to talk about legitimacy in general terms; the different types must be discussed separately and specific examples given.

Types of legitimacy

The numerous historical types of governmental legitimacy may be classified into two broad groups: numinous and civil.

Numinous legitimacy. The dominion of a *god-king*, of which ancient Egypt offers perhaps the most impressive example, is the theological doctrine according to which every pharaoh is himself (among other things) the god Horus, son of Osiris. The doctrine seems to go back to the very origin of the empire. The underlying myth of the birth

of Horus, repeated, as it were, in every accession to the throne, provided the Egyptian kingship with a powerful guarantee of identity and continuity, the appearance of eternity. The pharaoh is, as Henri Frankfort (1948) put it, the epiphany of the god, as distinct from the Hellenistic or late Roman institution of the apotheosis granted to an individual emperor (for example, Alexander the Great). The pharaoh's empire is god's empire. Obedience is not merely a political necessity but a religious obligation. Obviously, legitimacy of this sort is a matter of might rather than of right and transcends all juridical explanation.

The *godly origin* of the king, more specifically the king being the son of god, is a concept close to that of the godliness of the king. The early pharaoh was, indeed, both god and son of god. The phenomenon of being the son of god does not belong to antiquity alone, however; it constitutes an essential element of the Christian faith.

Divine vocation as a principle of legitimate government (whether temporal or spiritual) must be distinguished from divine origin. *Dominus noster Jesus Christus nos ad regnum vocavit* ("Jesus Christ our Lord called us to the throne"), claimed Henry IV in his struggle against Pope Gregory VII, and this understanding of the foundation of his office, and of his personal rulership as well, strictly followed the traditional pattern of the medieval Roman emperors. Charlemagne had considered himself as a *Deo coronatus* ("crowned by God"), and he also seems to have been the first king to attribute to himself the famous formula of *Dei gratia* ("by the grace of God"). The Christian *sacerdotium* ("priesthood") derived its legitimacy, and still does, from a source very similar to that of the *regnum* ("kingship"); according to official doctrine, the papal office is based on Christ's designation of St. Peter, which continues to sanctify and legitimize the rule of every successive pope. For centuries both king and priest were considered the embodiment of the institution of the vicariat. The controversy between them was not about their respective legitimacy as such, but rather about the question whether priestly coronation and consecration were of constituent or merely affirmative significance for the *regnum*.

Inspiration is a numinous basis of legitimate government that has not produced lasting governmental institutions to the degree the three previous bases have. Moses is the foremost example of numinous inspiration, and his name is cited in Christian political philosophy whenever government by inspiration and revelation is discussed. The later prophets of ancient Israel could be considered as performing the function in government that has

since come to be called the opposition. Time and again prophecy (in the sense of a mission based on direct revelation of a superior will) has inspired powerful political movements, often of a revolutionary kind. The Puritan revolution is a prominent example. Such superior will is not necessarily of a divine nature; Marx, for example, refers to history, and the Bolshevik party is guided by the will of history, of which the party claims to have a (quasi-theological) scientific knowledge.

Civil legitimacy. Civil legitimacy exists when a system of government is based on agreement between equally autonomous constituents who have combined to cooperate toward some common good. The polis is one paradigm, especially if understood in accordance with Aristotle, who defines it as "an aggregate of citizens, or in other words, of men possessing access to office and therefore either actual or possible rulers" (*Politics* III, 130). Medieval confederacies, viewed not as aggregates of citizens but as aggregates of autonomous estates, form another type of commonwealth, deriving their legitimacy from agreement, or *conjunctio*. Switzerland is an example of this type of commonwealth, the confederacy having survived Switzerland's transformation into a federal state. The institution of assemblies of estates (as for example, the French États Généraux, the old German Reichstag, or the unreformed English Parliament) is another example of an aggregate of autonomous entities, although it is of a very different structure and importance from the confederacy. Finally, every modern constitutional system, or more specifically, every system of representational government is founded either on a basic agreement to follow certain rules or at least on a justifiable assumption that a basic agreement to follow certain rules exists. These rules include the government's obligation to protect civil rights and liberties and to pursue the common good.

Modern constitutional government makes one characteristic of civil legitimacy particularly clear: governmental offices are ordered by trust rather than exercised by dominion. This characteristic is expressed in the institution of periodic elections. In recent times popular elections have become so predominant a criterion of legitimacy that almost every nation feels obliged to pay lip service to the institution of elections, no matter what its system of government [see ELECTIONS].

History and interpretations of the concept

Etymology. The word *legitimus* is classical Latin, while *legitimitas* seems to occur first in medieval texts, and, even then, only rarely. The Roman form means lawful, according to law.

While the word was used in all spheres of juridical relations, there are definite political overtones: Cicero uses *legitimum imperium* and *potestas legitima* in the sense of powers or magistrates constituted by law. His concept of the *justus et legitimum hostis* ("enemy by right and by law") is revealing; this enemy is to be distinguished from a robber or pirate and is *legitimus* because treaties are concluded with him, and concluding treaties constitutes a common ground of law (*De officiis* III, 108). Occasionally Cicero's usage seems to approach the meaning of hereditary succession: he wrote of dominions given by the tyrant Dionysius to his son, as *quasi justam et legitimam potestatem* ("his by right and by law") (*De natura deorum* III, 84).

The medieval meaning is very different: *legitimus* is what conforms to ancient custom and to customary procedure. The word begins to be applied to persons: *electi sunt quatuor legitimi viri communi assensu* ("four duly constituted men were chosen by common consent") (from a monastery charter, quoted in Du Cange's *Glossarium mediae et infimae latinitatis*) which means qualified persons (*boni homines*) who can testify and guarantee some juridical action to which they give lawlike validity by their very presence, as custom requires. There is, indeed, something to be said for interpreting the medieval *lex* as indicating the particular customary procedure of an appropriate council or assembly composed of members of the family or the judiciary whose resolution or assent gives legitimacy to the respective decisions. *Legitima auctoritas* ("legal authority") is thus sometimes opposed to *regale preceptum* ("royal warrant") just as *legitima potestas* ("legal power") is opposed to *tyrannica usurpatio* ("dictatorial seizure of power"). In these cases the word legitimate points to the element of constituted rule and order, but included in the meaning is the assembly itself to which the rule refers. The 1338 Bavarian electoral law of Emperor Louis states that he who is elected by the electors *ex sola electione censeatur . . . pro vero et legitimo imperatore* ("by the sole process of election he shall be constituted . . . emperor in truth and in law") instead of having to wait for papal consecration and other sanctifying ceremonies. Here the meaning of *legitimus* appears to come very close to its modern sense by adding the element of consent to the original *veritas* of the elected emperor. This idea of consent is precisely the element of meaning which remains in modern usage. Popular consent, although not the whole essence of legitimate government, is one of its most important criteria.

Because the word legitimacy has had so many

different meanings, the kinds of problems considered relevant to a discussion of legitimacy have also varied. For example, Plato's idea of justice bears on the problem of legitimacy. The same is true of Aristotle's concept of the best constitution and his distinctions between good and bad forms of monarchy, aristocracy, and democracy (*Politics* III). In the course of the medieval revival of interest in Aristotle, his discussion of king and tyrant became particularly important. Later, Thomas Aquinas drew a much sharper line between king and tyrant than Aristotle had done and thus came close to a theory of legitimate and illegitimate government. (The king is pursuing the *bonum commune*, the tyrant his *bonum proprium*.)

Augustine. Augustine declared that it was impossible for any community or government outside the City of God to be legitimate. Empires, he stated (*De civitate Dei* IV, 4), are big gangs of robbers. By turning Cicero's definitions against him, he claimed to prove that the Roman Empire had never been a *civitas* ("state") or *res publica* ("commonwealth") in the true meaning of those terms. He traced the origin of temporal government back to either Cain—the murderer—or Abel—a citizen of God's city. The two *civitates*, he insisted, share only a mutual enmity. There is one respect in which the worldly *civitas* seems to be justified: its desire for peace is a *bonum* ("good"), which through its imperfection points to the perfect and eternal peace of the heavenly city. Since legitimacy thus applies exclusively to the City of God, kingdoms must demonstrate that their subjects are Christ's people, just as kings must demonstrate that they are Christ's vicars. This need, which existed from the time of Augustine on through the Middle Ages, may explain a good deal of medieval political theology and "christology" (Kantorowicz 1957). It may also explain the similarity of claims made by the Roman church and the Roman Empire: *Extra civitatem Dei nulla legitimitas* ("No laws are binding save those of the City of God") [see AUGUSTINE].

Marsilius of Padua. Marsilius rediscovered the concept of the polity as an autonomous entity not in need of spiritual approbation or interpretation. His *Defensor pacis* (1324) represented a bold revolution in political thought. He denied the church any right of dominion, and he based *regnum* and *imperium*, like any *principatus* ("civil power") on the constitution of the human society and the consent of the people, using Aristotle's explanation of the polis as his main source. His astonishing book served the cause of Louis of Bavaria in his struggle with Pope John XXII but did so in a com-

pletely novel way: the foundation of imperial legitimacy was neither God's institution and vocation nor the theory of *translatio imperii* ("imperial succession") but, instead, constitutional election. Marsilius thereby cut the bond of theological legitimation that had united church and empire for over five hundred years [see MARSILIUS OF PADUA].

John Locke. Locke, the great revolutionary political thinker of seventeenth-century England, was, like Marsilius, an Aristotelian and a developer of a novel theory of civil legitimacy. While Marsilius' polemical attack was directed at papal domination and intervention, Locke's analysis of the nature of government started with an attack on the divine right of kings. He used Robert Filmer's *Patriarcha* as his text and demolished its arguments one by one in the first part of *Two Treatises of Government* (1690). Having destroyed the theory of the divine right of kings, he went on to build a totally different theory of government, according to which kingship was an office created by human agreement that served the common good of those agreeing to create it. Certainly, Locke's celebrated compact, from which political society originates, is concluded in order to preserve the natural rights of the contracting parties, but what matters more with regard to the question of legitimacy is that monarchy, as indeed all political institutions, is based on agreement and on the consent of the people. Locke served the cause of the Whig party and its Glorious Revolution against the Stuarts as Marsilius had served the Imperial party against the pope [see LOCKE].

Joseph de Maistre. De Maistre was a leading nineteenth-century advocate of legitimism and a prime opponent of Locke and his revolutionary views. He argued that Locke's concept of law was actually the outcome of human agreement and not of natural right. Condemning Locke's interpretation, he claimed that man cannot make a constitution because *toute constitution est divine dans son principe*. De Maistre conceived of the divine right of kings in a dynastic sense; it is the royal family rather than the royal office that has been chosen by God. He gave no explanation of the origin of a given dynasty's power, other than through the paradoxical process of *usurpation légitime*. Royal families exist, he stated, and this fact is the most telling sign of their legitimacy. In this view hereditary succession is an essential element of legitimate rule. *Des constitutions politiques* (1809) served the cause of the Bourbon restoration and, more specifically, of Talleyrand's introduction of legitimist doctrine into Europe. Although legitimism as a political force ended in France with the

July revolution of 1830, legitimist ideas dominated nineteenth-century discussions of legitimacy.

Modern discussions

Modern scholarly discussions of legitimacy can best be covered by reviewing three writers who dealt with the general notion of legitimacy: Max Weber, Carl Schmitt, and Guglielmo Ferrero. (From this selection of a sociologist, a lawyer, and a historian, it is apparent that the problem of legitimacy is of concern to many disciplines other than political science.)

Max Weber. Weber was the first to discover the universal applicability of the notion of legitimacy and therefore the first to use the term for classifying and comparing a great number of sociopolitical phenomena. The legitimists' preoccupation with dynastic succession had narrowed the meaning of the word "legitimacy," and this narrow usage had continued for almost a century. Weber's use of legitimacy helped deprive it of this specific historical connotation. Weber's typology of modes and sources of legitimacy forms part of his sociology of dominion (*Herrschaftssoziologie*) and is to be found in that monumental fragment *Wirtschaft und Gesellschaft* (1922). Legitimate dominion is not distinguished from illegitimate dominion. Instead, within the general framework of a value-free description of social patterns, the plurality of legitimacies becomes apparent. Weber seemed to assume that in legitimate dominion of any type, legitimacy is based on belief and elicits obedience. However, he did not discuss the general sense of legitimacy and instead concentrated on the pure types of legitimacy: the traditional, the charismatic, and the rational. His three types together cover the whole range of such phenomena. (Although these terms have provided the impetus for much empirical research, whether they provide the best classification of the empirical material they have helped unearth is still questionable.) By traditional legitimacy Weber understood mainly patriarchal and feudal forms of order and dominion. Here the objection may be made that the sanction of tradition plays its part in almost every kind of legitimacy, from constitutional systems to charismatic ones. Weber's notion of charisma is so closely associated with the uniqueness of prophets, heroes, and other leaders that it is difficult to understand the striking durability of certain historical systems based on the charisma either of kinship or of office. Weber himself had some doubts about the rationality of the third type: rational legitimacy. However, he never described the precise nature of the belief in legality which he placed

at the bottom of legal and bureaucratic dominion. There is almost no place left in his system for civil government in its proper sense. Democratic legitimacy occurs only as a reversion of charismatic leadership and is another concept that cannot be handled in his system. Whether laws are granted or agreed upon did not basically affect Weber's defiant and somewhat bitter "realism" [see WEBER, MAX].

Carl Schmitt. The problem of democratic legitimacy was, for obvious reasons, urgently discussed in the late years of the Weimar Republic. Schmitt's contribution to the discussion was his largely polemical treatise, *Legalität und Legitimität* (1932). The distinction between legality and legitimacy goes back to the French legitimist writers and is most sharply made in M. de Bonald's *Essai analytique sur les lois naturelles de l'ordre social* (1800). Although Schmitt did not define the terms of his title, he seemed to say that the state with parliamentary legislation lacks legitimacy altogether. "Fifty-one percent of parliamentary votes make for law and legality," he stated somewhat sarcastically, without ever asking why the remaining 49 per cent accept the majority decision, although this acceptance is, after all, the basic prerequisite of any constitutional system. Schmitt considered the plebiscitary elements of the Weimar constitution to be legitimizing factors, and he therefore pleaded that these factors be made the basis of an amended constitution. Schmitt's critics pointed out that his caesarist version of democracy was just as formalistic and neutral as to values as the parliamentary majority rule which he attacked (Kirchheimer & Leites 1932/1933). Schmitt's treatise both mirrored the lack of basic consent that characterized the Weimar Republic and was responsible for increasing that lack of consent [see SCHMITT].

Guglielmo Ferrero. Neither Weber's pattern of rationality and legality nor Schmitt's notion about the plebiscitary legitimation of democratic leadership answered the basic question: What is the core of democratic legitimacy? One significant solution was offered by Ferrero, who described democratic legitimacy as resting on two "pillars": majority and minority, or government and opposition. His formula broke the spell of the Rousseauian fiction of a general will (*volonté générale*) and avoids the dangerous drawbacks of considering majority rule as the essence of democracy. Hopefully this illuminating concept will be tested by comparative studies.

Apart from the particular problems already mentioned, there are many important questions about legitimacy that deserve further study. Among them

are the partly logical question of the universality of the concept and the partly ethical question of how to resolve conflicts of legitimacies both in theory and in practice.

LEISURE

Some authors hold that leisure has existed in all civilizations at all periods. This is not the view that will be taken in this article. Time-out is of course as venerable an institution as work itself. But leisure has certain traits that are characteristic only of the civilization born from the industrial revolution.

In the earliest known societies, work and play alike formed part of the ritual by which men sought communion with the ancestral spirits. Both these activities, although their functions differed at the practical level, had the same kind of meaning in the essential life of the community. Religious festivals embodied both work and play. Moreover, work and play were often combined. Conflict between them was either inconsequential or nonexistent, since play entered into work and became part of it. However, it would be going too far to view the shamans or witch doctors, who were exempted from ordinary labor, as a primitive form of "leisure class" in Veblen's sense. Shamans and witch doctors undertake to perform magical or religious functions that are regarded as essential to the community. "Leisure" is not a term that can be applied to societies of the archaic period.

Nor was leisure, in the modern sense, to be found in the agrarian societies of recorded history.

The working year followed a timetable written in the very passage of the days and seasons; in good weather work was hard, in bad weather it slackened off. Work of this kind had a natural rhythm to it, punctuated by rests, songs, games, and ceremonies; it was synonymous with the daily round, and in some regions began at sunrise to finish only at sunset. After work came relaxation; but even then, it was hard to tell where one ended and the other began. In the temperate zones of northern Europe, during the long winter months, the period of hard work would give way to a kind of semi-active existence during which the struggle for survival was nearly always hard. The deadly cold was regularly accompanied by famine and disease. Inactivity, under such circumstances, was something to be endured; followed (as it too often was) by a train of misfortunes, it certainly had none of the characteristics of leisure as we understand it today.

The cycle of the year was also marked by a whole series of sabbaths and feast days. The sabbath belonged to religion; feast days, however, were often occasions for a great investment of energy (not to mention food) and constituted the obverse or opposite of everyday life. But the ceremonial aspect of these celebrations could never be disregarded; they stemmed from religion, not leisure. Accordingly, even though the major European civilizations knew more than 150 workless days a year, we cannot use the concept of leisure to analyze their use of time. Let us take the example of France. In his *Projet d'une dîme royale* (a revolutionary proposal for impartial direct taxation, which was published in 1707 and immediately suppressed) Sébastien Le Prestre de Vauban used the term "unemployed" to denote these workless days; among them he singled out the "holidays"; such days were often imposed by the church, against the will of the peasants and artisans, in order to promote the carrying out of spiritual obligations. Thus the poor man in one of La Fontaine's fables ("Le savetier et le financier") is made to complain that Monsieur le Curé "is always burdening us with a sermon on some new saint" (II. 28-29). In France at the beginning of the eighteenth century, there were 84 "holidays" of this sort, and to these should be added an average of about 80 days a year on which work was impossible because of "illness, frost, or personal business" (Vauban [1707] 1943, p. 18). Thus by the end of the seventeenth century, according to Vauban, French peasants and artisans (some 95 per cent of the labor force) had to reckon with 164 workless days a year. In those poverty-stricken times the majority

of such days were not chosen; rather, they were imposed either by religious requirements or by lack of work.

Aristocratic and courtly leisure. Some authors, of whom de Grazia (1962) is representative, trace the origins of leisure to the way of life enjoyed by certain aristocratic classes in the course of Western civilization. But, in my opinion, neither the idle state of the ancient Greek philosophers nor even that of the gentry in the sixteenth century can be given the name of leisure. Such financially and socially privileged classes, cultured or not, paid for their own idleness with the work of their slaves, peasants, or servants. Such idleness cannot be defined in terms of its relation to work, since it neither complements nor rewards work but rather takes the place of work altogether. Of course, the aristocratic way of life has contributed in no small measure to the refinement of human culture; its ideal man was freed from work so that none of his capacities, physical or mental, should fail to be developed to the highest level. In ancient Greece, philosophers associated this ideal with wisdom; Aristotle himself argued that the work of slaves (that is, almost any form of manual labor) was incompatible with nobility of mind, and it is significant that the Greek word for having nothing to do (*scholē*) also meant "school." The courtiers of Europe, after the end of the Middle Ages, both invented and extolled the ideal of the humanist and the gentleman. The idleness of the nobility never lost its connection with the very highest values of civilization, even though many of the nobles themselves might have been mediocrities or scoundrels. Nevertheless, "leisure" is not a suitable term for referring to the activities of these idle elites, since leisure in the modern sense presupposes work.

Modern leisure. For leisure to become possible in the life of the great majority of workers, two preconditions must exist in society at large. First, society ceases to govern its activities by means of common ritual obligations. At least some of these activities (work and leisure, among others) no longer fall under the category of collective rites but become the unfettered responsibility of the individual, even though the individual's choice in the matter may still, of course, be determined by more impersonal social necessities. Second, the work by which a man earns his living is set apart from his other activities; its limits are no longer natural but arbitrary—indeed, it is organized in so definite a fashion that it can easily be separated, both in theory and in practice, from his free time.

These two necessary conditions exist only in

the social life of industrial and postindustrial civilizations; their absence from archaic and traditional agrarian civilizations means the absence of leisure. When the concept of leisure begins to infiltrate the rural life of modern societies, it is because agricultural labor is tending toward an industrial mode of organization and because rural life is already permeated by the urban values of industrialization. The same can be said of the agrarian societies of the "third world," which are in the process of raising themselves to the pre-industrial level.

Definition of leisure

Having outlined the nature of leisure in general, we can now proceed to a more specific definition, since the numerous studies of leisure made during the last thirty years allow us to describe with some exactitude how the concept may and may not be applied. In the first place, leisure should be distinguished from free time, that is, time left free not only from regular employment but also from overtime and from time spent in travel to and from the work place. Free time includes leisure, as well as all the other activities that take place outside the context of gainful employment. The personal needs of eating, sleeping, and caring for one's health and appearance, as well as familial, social, civic, and religious obligations, must all be attended to in one's free time. Leisure, by contrast, will be described here as having four basic characteristics, two of which can be called negative, since they refer to the absence of certain social obligations, and two positive, since they are defined in terms of personal fulfillment. In a 1953 survey of concepts of leisure based on a sample of French laborers and white-collar workers, it was found that, in nearly every case, these four characteristics were closely associated in the mind of the respondent.

Freedom from obligations. Leisure is the result of free choice. To be sure, leisure is not the same thing as freedom, and it would be wrong to say that obligations have no part in leisure at all. However, leisure does include freedom from a certain class of obligations. It must, of course, be conceded that leisure, like other social phenomena, is subject to the operation of social forces. In the same way, since it is an activity, it must depend, like every activity, on social relationships and therefore on interpersonal obligations such as contracts or even agreements to meet at a certain time and place. It is likewise subject to the obligations that may be imposed by any of the groups and organizations, from athletic teams to film societies,

that minister to its needs. But leisure does imply freedom from those institutional obligations that are prescribed by the basic forms of social organization. With respect to these institutional obligations, the obligations arising from leisure, considered as a form of social organization, always have a secondary character from society's viewpoint, regardless of how heavy they may be. To employ a dialectical mode of reasoning, leisure both implies and presupposes the existence of the fundamental obligations that are its opposite; the latter must cease before the former can begin, and each can be defined only in terms of the other.

Leisure, then, consists first and foremost in freedom from gainful employment in a place of business; similarly, it implies freedom from study that is part of a school curriculum. Leisure also includes freedom from the fundamental obligations prescribed by other basic forms of social organization such as the family, the community, and the church. Let us call this class of institutional obligations "primary obligations." Conversely, when a leisure activity becomes part of one's job (like sport to an amateur turned professional), one's studies (like a film show that all members of the school must attend), one's family life (like a Sunday walk), or one's religious or political obligations (like a political mass rally), then its nature, from a sociological point of view, undergoes a change even when its technical content has not changed at all and it affords the same satisfactions as before.

Disinterestedness. The disinterested character of leisure is the corollary, in terms of means and ends, of its freedom from primary obligations. Leisure is not motivated basically by gain, like a job; it has no utilitarian purpose, as do domestic obligations; unlike political or spiritual duties, it does not aim at any ideological or missionary purpose. True leisure precludes the use of any physical, artistic, intellectual, or social activity—in short, of any form of play—to serve any material or social end whatsoever, even though leisure, like any other activity, is subject to the laws of physical and social necessity.

It follows that, if leisure is governed in part by some commercial, utilitarian, or ideological purpose, it is no longer wholly leisure. Such leisure retains only part of its nature; we will therefore call it "semileisure." Under these conditions it is as if the circle of primary obligations partially obscured the circle of leisure; semileisure is the area where the two circles intersect. This situation exists when the athlete is paid for some of his appearances, the angler sells part of his catch,

the gardener with a passion for flowers plants a few vegetables for his own consumption, or the ardent handyman repairs his own house; it can even happen when someone attends a municipal function more for the show than the ceremony, or when an office worker reads a highbrow novel so that he can let the head of his department know that he has read it.

Leisure and diversion. We have defined what leisure is *not* by stating its relationship to the obligations and limits imposed by the basic forms of social organization. In order to define what leisure is, it is necessary to state its relationship to the needs of the individual, even when the individual fulfills these needs as a willing member of a group. In nearly all the empirical studies, leisure appears to be distinguished by a search for a state of satisfaction—a state that is sought as an end in itself. This activity is of a pleasure-seeking nature. To be sure, happiness is not simply a matter of leisure, since one can be happy while carrying out basic social obligations. But the search for contentment, pleasure, and delight is one of the fundamental characteristics of leisure in modern society. In this connection, Martha Wolfenstein (1951) has spoken of “fun morality.” When the desired state of satisfaction either passes or begins to wear off, the individual tends to give up the activity in question. Nobody is tied to a leisure activity by material need or by moral or legal obligations, as is the case with the activities of getting an education, earning a living, or carrying out civic or religious ceremonies. Although social pressure or habit may run counter to his decision to give up, the question of whether or not he is contented weighs more heavily with the individual in his leisure than in any other form of activity. The prime condition of leisure is the search for a state of contentment; it is enough to say “That interests me.” This state can consist in the denial of all tension, study, or concentration; but it can just as well consist in voluntary effort or even in the deferment of gratification. Whether the avocation involves battling against the elements, against a competitor, or against oneself, the effort of perfecting one’s performance or one’s wisdom can be greater than that spent on one’s regular occupation and may even approach the intensity of religious discipline. But it is an effort and a discipline that is chosen voluntarily, in the expectation of an enjoyment that is disinterested. The search for diversion is so fundamental to leisure that when the expected delight or enjoyment fails to materialize, leisure itself is denatured—a situation that is summed up by such remarks as “It was

boring” or “It wasn’t entertaining.” Leisure, in such cases, is no longer wholly itself, but suffers impoverishment.

Leisure and personality. All the manifest functions of leisure, to judge from their effect on the persons concerned, answer to individual needs, as distinguished from the primary obligations imposed by society. Thus leisure is directly associated both with the possibility that the individual may deteriorate (for instance, if he becomes an alcoholic), and with the fact that the individual is free to defend the integrity of his personality against the attacks of an urban industrial society that is becoming less and less natural and more and more regimented and run by the clock. It is associated with the realization, whether encouraged or discouraged, of unbiased human potentialities—in short, with the whole man. Such realization, whether or not it accords with social needs, is conceived as an end in itself.

The positive functions of leisure can be summed up as follows. (1) It offers the individual a chance to shake off the fatigue of work that, because it is imposed, interferes with his natural biological rhythms. It is a recuperative force, or at least an opportunity to do nothing. (2) Through entertainment, whether of a sort permitted or forbidden by society, leisure opens up new worlds, both real and imaginary, in which the individual can escape from the daily boredom of performing a set of limited and routine tasks. (3) Finally, leisure makes it possible for the individual to leave behind the routines and stereotypes forced on him by the workings of basic social institutions, and to enter into a realm of self-transcendence where his creative powers are set free to oppose or to reinforce the dominant values of his civilization. Leisure in the truest sense of the word fulfills all three of these basic functions and satisfies the human need that corresponds to each. Leisure that fails to offer all of these three kinds of choice at any time is leisure that, with regard to the needs of the human personality in modern society, must be considered seriously defective.

The sociology of leisure

The importance of leisure in the development of our civilization was foreseen by social thinkers from the very beginning of industrial society. In some contexts Marx treated work in itself as the first need of man, but in others he qualified this statement by adding that work would become fit for man only when it had been transformed by collective ownership, automation, great increases in free time, and the transcending of the antithesis

between work and leisure by the creation of the unalienated "whole man." Comte and Proudhon differed from Marx in their conceptions of the society of the future, but all three attached great importance to conquering leisure by means of technological progress and social emancipation. And they all associated the growth of leisure with raising the workers' level of education and increasing the part played by them in public life.

The realities of leisure in the twentieth century, as sociologists have observed them in both socialist and capitalist societies, have turned out to be more complex and less easily defined. The first modern pamphlet in favor of leisure for the worker was written in Europe by Paul Lafargue (1883), who was a militant socialist; its title was *Le droit à la paresse* ("The Right to Be Lazy"). But it was in the United States that the foundations were laid for the sociology of leisure by Thorstein Veblen's *The Theory of the Leisure Class* (1899). Veblen analyzed the different types of idlers that he found among the bourgeoisie; he exposed the conspicuous consumption indulged in by the bourgeoisie in its quest for social status. But it was not until the 1920s and 1930s that there appeared, both in Europe and in the United States, the first empirical studies of leisure by sociologists. The introduction of the eight-hour day awakened both the hopes and the anxieties of social reformers, who wondered whether the extra free time would be used for self-improvement or for dissipation. In the U.S.S.R., the work of Strumilin (1925) inspired research on the "time budgets" of individuals, at the same time that the Soviet government developed an official policy on the organization of leisure. In 1924 the International Labor Office organized the first international conference on the free time of the worker; it was attended by 300 delegates from 18 nations. There was a general feeling that as the time spent on work decreased, leisure activities would have to become more organized (*International Labour Review* 1924). Research projects were launched in the United States; the most famous of them, by Robert and Helen Lynd (1929; 1937), devoted much space to the study of leisure activities, both traditional and modern, and to the way in which they were organized. In 1934 George A. Lundberg, in a study that has since become a classic, defined leisure as the *opposite* of those activities that are on the whole instruments to other ends rather than ends in themselves (Lundberg et al. 1934).

After World War II the sociology of leisure took on a new dimension and new levels of meaning. The United States was beginning to grapple with

the problems of mass society, namely, mass consumption and mass culture. In this new context the paradox of leisure nourished a whole new crop of studies. In 1950 David Riesman's *The Lonely Crowd* appeared, a work of which nearly one million copies have been printed and which has had a great influence not only in the United States but in every part of the world. Riesman argued in favor of the hypothesis that modern man, viewed in terms of his social character, has known only two revolutions. The first began with the Renaissance, when the "tradition-directed" man whose social character had been derived entirely from the community began to be governed by the norms and values of the family and so became "inner-directed." Finally, about the middle of the twentieth century, the second of these revolutions appeared in those countries that had entered the stage of mass consumption and mass culture. In this period man has begun to be governed by the norms and values conveyed by the mass media of communication on the one hand and by peer groups on the other. Under such circumstances man becomes "other-directed." Reflections on mass leisure were therefore central to Riesman's theoretical perspective. A few years later there appeared the first collections of readings on the topic of "mass leisure" (Larrabee & Meyersohn 1958; Rosenberg & White 1957). Finally, decisive progress was made in the empirical verification of these new ideas on the relationship of leisure and culture in mass society (see especially Havighurst & Feigenbaum 1959; Wilensky 1964).

In Europe, during the same period, the sociology of leisure has made almost equally remarkable progress; the work of Georges Friedmann, in particular, gives a special place to the role of leisure in "relocating" man in a civilization dominated by technology. In England B. S. Rowntree and G. R. Lavers' *English Life and Leisure* (1951) has inspired a whole series of sociological monographs and research studies that have evoked considerable response in other countries, especially Holland. Large-scale public-opinion polling from 1954 onwards on the way in which young people spend their leisure is beginning to result in vigorous government programs stressing character building and the provision of facilities for leisure. With these problems in mind, in 1953 Joffre Dumazedier began the research that finally resulted in *Vers une civilisation du loisir?* ("Towards a Civilization of Leisure?" 1962) and in *Le loisir et la ville* ("Urban Leisure") (Dumazedier & Ripert 1966).

In the socialist countries, likewise, the study of leisure has undergone expansion. For instance, in

the U.S.S.R. during the period 1956-1962 the gradual replacement of the eight-hour working day by one of seven hours stimulated renewed inquiry, in the tradition of Strumilin, into time budgets and leisure-time activities (Prudenskii 1964; Petrosian 1965). The first empirical study of leisure in a socialist setting that made use of the very latest sociological research methods took place in Yugoslavia (Ahtik 1963). The empirical study of sociology has also taken remarkable strides forward in Poland, thanks to the efforts of the Center for the Study of Mass Culture, which is affiliated with the Polish Academy of Sciences.

Applications. The sociology of leisure has made it possible, for the first time, to draw empirical comparisons between the working class culture of different or contrasting political and economic systems. In 1956 the first comparative study of leisure in Europe was launched, dealing with the leisure of workers in six European cities, each in a different country. The countries included in the survey were Yugoslavia, Poland, France, Finland, Denmark, and the German Federal Republic.

The vitality of the sociology of leisure has given rise to a number of problem-oriented approaches. Leisure has been studied in its relation to work (Friedmann 1958; Riesman 1964), the family (Scheuch 1960; Anderson 1961), religion (Pieper 1948), politics (Lipset et al. 1956), and culture (Kaplan 1960; Dumazedier 1962; Wilensky 1964). It has been treated as a temporal framework (Prudenskii 1964; Petrosian 1965; Szalai 1966), a complex of activities (Littunen 1962), a system of values (de Grazia 1962), and in several other ways.

The sociology of leisure also exhibits great methodological variety; it is not marked by adherence to any particular method, but by use of any and all available methods. Thus, although empirical studies are more common, we find a strong historical tradition, from Veblen to Riesman and de Grazia. The most important project now in progress concerns time budgets; it is a comparative study, using national samples from the German Federal Republic, Belgium, Austria, France, Hungary, Poland, and the U.S.S.R., directed by Alexander Szalai, a Hungarian scholar, under the auspices of the European Center for Coordination of Research and Documentation in the Social Sciences.

It is to be expected that in the future the different industrial and preindustrial societies will stand in increasing need of research, especially in order to: (1) measure the effective limitations of time, distance, money, and so on, that are preventing the transformation of free time into genuine leisure

in the life of numerous classes and categories of workers; (2) evaluate the resources available for leisure in the cultural development of whole societies.

In the postindustrial societies now entering the phase of mass consumption, specific problems have arisen, and will continue to arise with even greater intensity. It is the ambivalence of leisure values in popular culture that will pose the greatest problems to sociologists. Will commitment to leisure values be balanced by commitment to occupational, associational, political, and spiritual values, or will leisure threaten all these other values, thus placing in jeopardy the active participation of citizens in directing the future of their society? Finally, since leisure values are themselves diverse, will the values of entertainment and unfettered personal development join forces to create a new ideal of individual happiness and social well-being? Or, on the contrary, will the values of entertainment, artificially hypertrophied by an irresponsible commercial system, come to play, in certain countries, the role of a new "opiate of the people," while in certain other countries a unilateral and oppressive government policy for leisure activities risks truncating the complex phenomenon of leisure, encouraging boredom and malingering by way of reaction? In the last analysis, the whole future of man in industrial and postindustrial civilization is bound up with the answers to these questions. Today, they are the most important questions facing the sociology of leisure.

LENIN

Vladimir Il'ich Ul'ianov (who in 1901 began to call himself Lenin) was born on April 22, 1870, in Simbirsk, now Ul'ianovsk, a provincial town on the Volga, one of six children in an educated middle-class family. When he died on January 21, 1924, near Moscow, he was acclaimed as "the greatest genius of mankind, creator of the Communist Party of the Soviet Union, founder of the Union of Soviet Socialist Republics, the leader and teacher of the peoples of the whole world." In different measure the events of his personal life, his intellectual life, and his active political life contributed to this metamorphosis.

His father, of lower middle-class origin, was a graduate of the university in Kazan and for many years taught mathematics and physics in secondary schools in the Volga region. In 1869 he was appointed a school inspector and, shortly afterward, director of the "people's schools" in Simbirsk province, thus earning the rank of nobleman. Ul'ianov's mother was a woman of indomitable character. Daughter of a country doctor with little money and a large family, she had received her schooling at home. The boy Vladimir, the second son, was an intelligent and conscientious student, and a good swimmer, skater, and chess player. He was much impressed by his father's talk of the "darkness" of life in the villages and of the arbitrary treatment of peasants by officials. A voracious reader, Ul'ianov became well acquainted at an early age with the writings of the great Russian authors,

from Pushkin through Turgenev to Tolstoi, and was especially interested in the works of Nekrasov; he was also aware of such protorevolutionary writers as Belinskii, Herzen, Chernyshevskii, Pisarev, and Dobroliubov. But there was no hint in these early intellectual activities that he would become a revolutionary.

The first blow to young Ul'ianov's happy existence was the death of his father in 1886. An even worse shock was the arrest, in March 1887, of his elder brother, Alexander, whose brilliant research on worms at the university in St. Petersburg had promised a bright future but who, unknown to his family, had been active in terrorist revolutionary circles. Alexander was executed for having plotted the assassination of the tsar. The Ul'ianov family, shunned by local society, moved to a village not far from Kazan. Ul'ianov was admitted to the university in Kazan, though only on the strength of a character reference from the director of the Simbirsk Gymnasium, father of Alexander Kerenskii, the man Lenin was later to overthrow.

Ul'ianov was arrested in December 1887 for his part in a student demonstration against a university rule that enjoined students from forming organizations. Expelled from the university and forbidden to go abroad for study, he threw himself into preparation for external examinations and was finally permitted to take these in the spring of 1891, thus winning a first-degree diploma from the law faculty of the university in St. Petersburg. For two years he held a job in a Samara law office; at the same time he was studying Marxism and engaging in open criticism of the *narodniki*, activities which he continued in St. Petersburg, where he went in 1893 "in quest of the proletariat." By the spring of 1895 he had become well enough known to be sent by his comrades to visit Georgii Plekhanov, the "grandfather of Russian Marxism," in Geneva. Before his return he met Paul Lafargue, son-in-law of Karl Marx, and the veteran German Marxist Wilhelm Liebknecht but was unable to see the dying Friedrich Engels.

That fall young Ul'ianov joined with L. Martov (pseudonym of Iulii O. Tsederbaum) and a handful of other intellectuals to form the so-called Union of Struggle for the Emancipation of the Working Class, which planned to publish an illegal newspaper, *Rabochee delo* ("The Workers' Cause"). The first issue was confiscated, and Ul'ianov was among those arrested. Imprisonment prevented him from participating in the vigorous strike movement of 1896, but with the aid of books borrowed from the leading libraries of the capital he was able to continue his study and writing. In February 1897 he

was released to make his arrangements for a three-year period of exile at the Siberian village of Shushenskoe in Yenisei province, near the modern coal basin of Kuznetsk. There he lived in a peasant hut, his main source of income being the government allowance of 8 rubles a month. A year later Nadezhda Krupskaiia, whom he had met in St. Petersburg in 1894, arrived with her mother for a visit and was permitted to remain in Siberia on the condition that she and Ul'ianov be formally married.

In Siberia, he continued his feverish literary activity, in particular pursuing his study of the spread of capitalist relations in the peasant villages. Aware of serious gaps in his education, he undertook a systematic study of quite diverse philosophical views, while also broadening his knowledge of the writings of Marx and Engels. He completed his first major work, *The Development of Capitalism in Russia* (1899a), published under the pseudonym Vladimir Il'in. It was at this time also that he read Eduard Bernstein's *Die Voraussetzungen des Sozialismus und die Aufgaben der Sozialdemokratie* ("The Prerequisites of Socialism and the Tasks of Social Democracy"). Bernstein's thesis, revising some basic tenets of Marxism, shocked Ul'ianov profoundly, and he was no less outraged by the *Credo* of the "Economists." He issued his own *Protest* (1899b) against this penetration of Russia by the revisionist heresy, and it was adopted by a conference of exiles in Siberia (meeting ostensibly to celebrate a child's birthday).

Political achievements

From this time on, Ul'ianov's consuming passion was the organization of a disciplined Russian Marxist party capable of effectively combating all revisionist tendencies. To this end, he felt, it was necessary to found an all-Russian Marxist newspaper. Released from exile at the beginning of 1900 but forbidden to reside in either of the two capitals or in university or major industrial towns, he promptly applied for permission to go abroad and in July was able to leave for Switzerland. In Geneva, Plekhanov's insistence on controlling the proposed newspaper so offended Ul'ianov that the project almost fell through. However, a compromise was reached whereby Ul'ianov was permitted to arrange for the publication of *Iskra* ("The Spark") in Munich; there Krupskaiia joined him in April 1901. The first number was printed (in Leipzig) in January 1901, and a monthly periodical, *Zaria* ("Dawn"), followed in December. It was in the course of this year that he began to sign his articles "Lenin."

It was in 1901 also that Lenin began to write his second—and most significant—major work, *What Is to Be Done?*, published at Stuttgart in March 1902. Meanwhile, disagreements between Lenin and his editorial colleagues in Switzerland multiplied; in particular, Lenin's insistence on emphasizing the "dictatorship of the proletariat" in connection with the formulation of an agrarian program irritated Plekhanov, who opposed Lenin's "polemics."

Mainly at Lenin's insistence it was decided to call the Second Party Congress to create an all-Russian party, a task at which the Minsk Congress of 1898 had failed. Lenin himself devoted immense effort, by voluminous correspondence with *Iskra* agents in Russia, to guarantee a workable majority of reliable delegates. The congress met in Brussels in the summer of 1903 but found it expedient to move to London. It was attended by 43 delegates, assigned 51 votes; of these, 44 could be counted on to support the *Iskra* position. With the support of his colleagues on the *Iskra* editorial board Lenin won adoption of his draft program, though two Economist delegates fought hard to include a reference to class consciousness as a precondition to establishment of the "dictatorship of the proletariat." However, a split developed among *Iskra* supporters over Lenin's effort to secure adoption of his version of the first paragraph of a party statute, embodying his conception of the dominance of a revolutionary elite. Despite the somewhat unexpected support of Plekhanov, Lenin's formulation was defeated; Martov's broader definition of party membership was adopted by a vote of 28–22, with one abstention. The subsequent withdrawal from the congress, over other issues, of the five delegates of the Jewish Bund and of two Economists changed the balance of strength. By vigorous caucusing Lenin was able to whip together a fairly solid bloc of 24 votes, which enabled him to carry the election of his candidates to the new editorial board of *Iskra* (now confirmed as the new party's "central organ") and to the new central committee. It was by virtue of these votes, not of the statistics of later party allegiance, that Lenin's followers for decades boasted the name *bol'sheviki* ("majority men").

Lenin's triumph was brief. Plekhanov soon abandoned Lenin's "hard" *Iskra* line, and control of the party and of its central committee passed to the *men'sheviki* ("minority men"). Lenin found himself doomed to years of bitter wrangling with his former colleagues. In the revolution of 1905 he was able to exercise almost no influence. He did not return to Russia until, with the October Mani-

fest, the autocracy had apparently surrendered. In Russia, he continued to denounce all socialists who would not follow him, and all liberals. After some wavering he supported boycott of the elections to the Duma, and he gave his blessing to, though he did not participate in, an abortive armed uprising in Moscow. After a few months of underground existence, of shifting from one hiding place to another, Lenin withdrew to the relative security of Finland. Pained by his failure to dominate the Fourth ("Unity") Congress of the Russian Social Democrats, in Stockholm (April–May 1906), he took some comfort from his successes at the Bolshevik-organized Fifth Congress in London (May 1907) and was considerably heartened by participation in the Stuttgart Congress of the Second International (August 1907), the first international congress he had ever attended. At the end of 1907 he abandoned his base in Finland and slipped back to Switzerland.

The next ten years were the bitterest and most difficult of Lenin's life. He became wholly occupied not with the direct struggle to combat capitalism and tsarism but with a preliminary, many-faceted battle to destroy the influence of all those who professed devotion to the cause of the proletariat, as he did, but who formulated its task in ways he considered unacceptable. Although Lenin was always ready to score a point at the expense of his rivals, he loudly and insistently denounced "opportunism" as the greatest brake on the progress of the socialist revolution. Thus, he worked himself into a position of almost total isolation within the revolutionary movement. This position, however, was ultimately to prove most advantageous to him. His name became one of the best known among the revolutionaries; but he was dissociated from all the failures of the other leading figures and thus was able, at a crucial moment, to offer fresh hope to the despairing.

In 1912, Lenin's Bolshevik adherents in Russia secured permission from the tsarist government to publish a newspaper called *Pravda* ("Truth"). Lenin at once moved from Switzerland to Cracow and then to Poronino, near the Austrian–Russian border. Here he could hope to keep in maximum contact with, and direct the policy of, the new organ. He could also supervise the activities of the "Bolshevik six" in the newly elected Fourth Duma. Lenin selected Roman Malinovskii to be their spokesman, unaware that he was on the police payroll. Although Bolsheviks from abroad were regularly arrested on their arrival in Russia, Lenin long remained obdurately blind to this circum-

stance, despite repeated protests from more sensitive friends.

On the outbreak of war in 1914 Lenin was arrested by the Austrian police on suspicion of espionage. The absurdity of the charge facilitated his release on condition that he return to Switzerland. There he remained, in devastating impotence, attending international socialist conferences at Zimmerwald and Kienthal, only to see the meager fruits of his vigorous efforts ruined by the subsequent defection of his allies. It is to this period that belongs the work of which Bolsheviks have remained most proud, *Imperialism, the Highest Stage of Capitalism*, completed in the summer of 1916.

At the end of January 1917, Lenin consoled himself—and all who would still heed him—with the thought that the tsar, fearing the outbreak of a bourgeois revolution in Russia, would not dare make a separate peace with Germany. Therefore, the war would continue, enormously enhancing the chances that Europe (not Russia) would begin the socialist revolution. Six weeks later, on March 15, 1917, to his surprise and delight Lenin learned from the Swiss newspapers that the Russian autocracy had collapsed and that a "Provisional Government" had been set up. A new danger loomed—the possibility that all elements in Russia might rally to the new regime. Lenin felt it was an urgent necessity that he reach Russia and prevent the Bolsheviks from making fools of themselves. The German government was likewise persuaded that Lenin's presence in Russia was an urgent need, though not for the same reasons. It was arranged, through Swiss intermediaries, that Lenin and other Russian exiles in Switzerland, whatever their political complexion, be permitted to travel incommunicado (on the "sealed train") across Germany. Via Sweden and Finland, Lenin reached Petrograd on the evening of April 16, 1917. From that moment, one might say, Lenin had no personal life, for his biography and the further history of the Russian Revolution became inextricably intertwined.

Lenin acknowledged that "Russia is now the freest country in the world"; yet he refused to take any part in enabling the new regime to establish itself. Instead he watched for every opportunity to overthrow it in the name of a new absolutism, "the dictatorship of the proletariat." He did seize power successfully on November 7, 1917, and thereafter, notwithstanding frequent vigorous opposition from tried associates, Lenin was in fact able to guide the ever-shifting policies of the new "Soviet" regime until he was incapacitated in May 1922 by

a paralytic stroke. Sufficiently recovered to partially resume his duties, he was rendered wholly impotent by a second stroke and remained so for almost a year before his final, fatal stroke.

Major writings

The explanation of Lenin's political success cannot be found in his intellectual achievements, for he was of no significance as an abstract thinker. His most scholarly work, *The Development of Capitalism in Russia* (1899a), was simply a tract to prove definitively the folly of the *narodnik* concept of the role of the peasantry in Russia. He showed that the peasantry was ceasing to be a uniform mass and was splitting into capitalist and proletarian sectors (a development of which Witte and Stolypin became aware independently). In Lenin's view this process should be encouraged by the abolition of landlordism, which was slowing the development of capitalist relations in the village. Thus, the proletarian, "depeasantized," element in the countryside would strengthen the urban proletariat, whose lack of numbers was compensated for by its concentration, fitting it to lead a mass movement of the village poor to overthrow tsarism and capitalism together.

In *What Is to Be Done?*—directed against the *narodniki*, and against the Economists as well—Lenin developed the thought that the working class, left to its own spontaneous strivings, would never become socialist. Only the conscious effort of "educated representatives of the propertied classes," i.e., the Marxists, would be able to "divert the labor movement, with its spontaneous trade-unionist striving, from under the wing of the bourgeoisie, and to bring it under the wing of revolutionary Social-Democracy." This viewpoint was embodied in the program adopted by the Second Congress, in preparation for which *What Is to Be Done?* had been published. It continued to dominate all Lenin's thinking and actions and is perhaps the very essence of "Leninism" as distinct from Marxism.

Imperialism, the Highest Stage of Capitalism has been hailed as "the most outstanding contribution to the treasury of creative Marxism" and as evidence of Lenin's stature as "a scholar of genius, a most conscientious researcher, and the greatest fighter for revolution" (Moscow [1960] 1963, p. 274). It did indeed assert as a scientific prediction that imperialism spells the doom of capitalism and, because it creates the objective conditions for world revolution, also represents the eve of socialist revolution. In other writings at this time, however, Lenin suggested that the "law of uneven develop-

ment" might make possible the victory of socialism in a single country.

Even less original than *Imperialism* was his other famous tract, *State and Revolution* (1917a), written after the failure of the July uprising as a blueprint for the immediate future. He argued that the existing "hypocritically democratic" regime was merely a "dictatorship of the bourgeoisie" and must be replaced by a "dictatorship of the proletariat," a term that Lenin never ceased to think of as meaning dictatorship of the Bolsheviks. He was careful to emphasize the distinction between the two stages, "socialism" ("from each according to his abilities, to each according to his labor") and "communism" ("from each according to his abilities, to each according to his needs"), a distinction that Stalin was later to cause to be written into the 1936 constitution. Lenin believed that although social inequalities would persist under "socialism," it was impossible to attain to "communism" without an indefinitely prolonged period of "socialism."

Political realism

Lenin's forte was an extraordinary ability, found also in men such as Bismarck, to analyze a given practical situation and to give things an unexpected push in the general direction in which he wished them to move. He did not rely on abstract ideas as guides to policy; he attacked Trotsky for using "abstract (and therefore empty) words." Although, like many other Russian middle-class youths of his generation, he was impressed by the grandiose aspects of Marxism, he never fully committed himself to their implications as worked out in western Europe. On the morrow of his return to Russia in 1917 he denounced "Bolshevik" pre-revolutionary antiques" on the grounds that they failed to grasp the "incontestable truth that a Marxist must take cognizance of real life, of the true facts of *reality*, and not cling to a theory of yesterday, . . . which like all theories . . . only comes near to embracing life in all its complexity. Theory . . . is grey, but green is the eternal tree of life" ([1917b] 1964, p. 45).

His leadership of the Bolsheviks during the revolution and in the still more chaotic years that ensued involved a shrewd following of events rather than a genuinely creative initiative. With the definite goal of seizure—and retention—of power in mind, he showed true realism, even adopting positions that to many seemed at the moment completely unrealistic.

His initial demand, in the "April Theses" (announced to his party colleagues the day after his arrival in Petrograd: see 1917c), for "all power to

the Soviet" surely seemed ridiculous, for the Bolsheviks were only a small minority in the Petrograd Soviet. Yet it turned out to be the only way to save the Bolsheviks from joining the Soviet majority in support of the Provisional Government and thus to absolve them from responsibility in the eyes of the masses later when discontents and disappointments had accumulated. (To be sure, this demand involved the Bolsheviks in the premature July uprising, from whose consequences they were rescued, however, by the Kornilov affair.)

It was realism, too, that prompted Lenin to insist on an armed uprising in November rather than wait for the "uncertain voting" at the Second Congress of Soviets. He was aware, as some of his associates were not, that the masses were not swinging to active support of the Bolsheviks, that disappointments and weariness had bred tremendous apathy, and that there was no likelihood of serious opposition to any group that would act with vigor, particularly if it could wrap itself in the cloak of the soviets and would promise speedy convocation of the long-dreamt-of Constituent Assembly.

His extrication of Russia from the war, similarly, was not the realization of a plan thought out in advance; it was the result of realistic yielding to facts as they gradually became obvious to him. The initial "Appeal to the Peoples and Governments of All Warring Countries" (1917d) simply called for a general armistice (Lenin then rejected a separate one) and conclusion of the "democratic peace" that had been proposed by the Provisional Government. Only after weeks of silence on the part of the Allies did Lenin approve of separate negotiations with the Central Powers, and only on the same "democratic" terms. When it became clear that the Central Powers would not make a separate peace on the basis of no annexations and no indemnities, Lenin addressed pointed questions to a congress of army representatives: If negotiations were broken off, would the Germans, despite the winter weather, launch an offensive? If they did, could the army fight or would it flee in panic? Lenin was tempted by Wilson's Fourteen Points address, of January 8, 1918, to contemplate renewal of the war with practical assistance from the Allies. Even in the face of a German ultimatum, Lenin advised dragging out the negotiations in the hope that the expected German revolution would break out and save Russia. Only when Trotsky's defiant "no war, no peace" declaration precipitated the final rupture of the negotiations did Lenin begin to insist on immediate acceptance of the German terms, arguing that, no matter how onerous the

Brest-Litovsk terms were, they would leave the Bolsheviks in control of an amputated Russia, with a "breathing spell" to consolidate their power in preparation for the inevitable "revolutionary war" against the whole capitalist world.

This same realism showed in his handling of the peasant question. Rejecting as irrelevant the criticism that the original Bolshevik decree on the land problem meant scrapping the established Bolshevik program in favor of the policy advocated by the Socialist Revolutionaries, Lenin had exclaimed, "We must follow life." If the Bolsheviks were to remain in power, the peasant masses must be acquiescent; otherwise there would be no food for the towns. When, however, the peasants had clearly tired of accepting worthless Bolshevik paper in exchange for their surplus grain, Lenin promptly abandoned his principle that "the general and basic source of any right to the use of agricultural land is individual labor." He called for a crusade—not, of course, against the peasantry but against the "village bourgeoisie"—to "carry the class war into the countryside" with the aid of the "village poor" (*Polnoe sobranie sochinenii*, vol. 36, pp. 368–369).

His attitude toward the Constituent Assembly also reflected keen appraisal of the realities of the moment rather than any previously elaborated ideological position. At the moment of the seizure of power, when the Bolsheviks still needed the semblance of democracy and there was at least some hope that the Bolsheviks and their Left Socialist Revolutionary allies might win a slender majority, Lenin had been willing to gamble on permitting the election of a Constituent Assembly. When, however, despite Bolshevik control of the power centers, the elections went overwhelmingly against the Bolsheviks and their allies, he flatly declared, "The Soviets are superior to any parliament, to any Constituent Assembly" (*ibid.*, vol. 35, p. 140). After it had met for one night, Lenin announced, "We will not give up Soviet power for anything in the world," and the assembly was dissolved (*ibid.*, vol. 36, p. 242).

Wherever one turns in examining the various policies for which at various times he fought so vigorously, the same theme recurs. Never did Lenin argue for action on the basis of ideas he had advanced in his major theoretical works. In combating the "Left Communists" (April 1920), he wrote them off as "doctrinaires of revolution," adding that "God himself has ordained that for a time the young should talk such nonsense." In advocating the abandonment of the policy of confiscating all surplus grain, the basic step in the introduction of the New Economic Policy, he argued: "We know

that only agreement with the peasantry can save the socialist revolution in Russia, unless revolution begins in other countries. . . . [The] peasantry is not content with the form of relations we have established with it . . . and will not go on living this way. . . . [We] are sober enough politicians to say right out: 'Let's reconsider our policy in relation to the peasantry'" (*ibid.*, vol. 43, p. 59). In demanding at the Third Congress of the Third International that that body switch from the aggressive position he had urged on it a year earlier, he acknowledged:

When we began the international revolution . . . [it] seemed clear to us that without the support of international world revolution the victory of a proletarian revolution was impossible. . . . In other large, capitalistically more developed countries the revolution has not broken out even yet. . . .

What must we do now? We need fundamental preparation of the revolution and deep study of its concrete development in advanced capitalist countries. . . . As for our Russian Republic, we must take advantage of this brief breathing spell to adapt our tactics to the zigzag line of history. (*ibid.*, vol. 44, pp. 36–37)

In celebrating the fourth anniversary of the seizure of power, Lenin admitted:

We thought—or, it would be more accurate to say, we assumed without adequate consideration—that by direct orders of the proletarian state we could get state production and state distribution of products going on a communistic basis in a land of petty peasants. Life showed us our mistake. . . . Not directly on the basis of enthusiasm, but . . . on the basis of *personal* interest, on the basis of *individual* [or *personal*; in Russian, *lichnyi*] incentive, on the basis of economic calculation, will you labor to construct the first solid footbridge leading in a land of petty peasants by way of state capitalism to socialism; you will not otherwise attain to communism. . . . This is what life has told us. This is what the objective course of development of the revolution has told us. (*ibid.*, vol. 44, p. 151, *italics added*)

. . . It is individual incentive that raises production; we need increase in production above all and no matter what. (*ibid.*, vol. 44, p. 152)

This "lesson in tactics," far more than his so-called testament penned in the interval between his first and second strokes, was the real guideline Lenin left to his successors.

LESLIE, T. E. CLIFFE

T. E. Cliffe Leslie (1827-1882), Irish sociologist and economist, was born in County Wexford and educated at Trinity College, Dublin. After graduation in 1847 he studied law in London, where he attended the lectures of Sir Henry Maine and was influenced by Maine's emphasis on the historical approach to an understanding of institutions. He was a member of Lincoln's Inn and of the Irish bar, but he never practiced. In 1853 he was appointed to the chair of jurisprudence and political economy at Queen's College, Belfast, a post he held until his death. His academic duties required his presence in Belfast for only a few weeks in the year, and the larger part of the time he resided in London.

Leslie was a prolific writer of essays, most of which were reprinted. He never published a full-length book, and after his death a biographical sketch reported that while traveling on the Continent he had lost a partially completed manuscript of a comprehensive work on English economic and legal history. His first publication, in 1851, "Self-Dependence of the Working Classes Under the Law of Competition," read before the Dublin Statistical Society, was a youthful performance along conventional lines. It stressed the force of competition and showed none of the originality or break with conventional economics which marked his later writing. In 1856 appeared the only one of his professorial lectures to be printed as such: *The Military Systems of Europe Economically Considered*, a defense of voluntary enlistment as against compulsory military service. His concern with military problems, both in their narrower economic aspects and in their broader historical and sociological bearing, continued for over a decade.

Beginning in the late 1860s Leslie's writings were concentrated for several years on the land problem, particularly in Ireland. He opposed home rule for Ireland but championed land reform and was critical of what he called "insolent theories of race." Drawing upon observations from several visits to the Continent, which brought him in close touch with the French economist and politician Léonce de Lavergne, he stressed the advantages of small agriculture holdings. In his views of the land problem he generally defended laissez-faire policies, and his emphasis was on elimination of legislative abuses in taxation and property rights rather than on positive policies of social welfare. He attacked entail and primogeniture, urged taxation more equitable to workers, and supported extension of the political franchise.

In the 1870s Leslie's main interest turned to economic methodology, apparently as an outgrowth of a cross-fertilization between his studies of the land problem and the ideas of Sir Henry Maine. Leslie had, however, already attacked prevailing theory: in connection with a discussion of Irish conditions (1870a), he had repudiated the wages fund doctrine, and he repeatedly criticized it as not squaring with the historical facts of wage determination. He criticized the "vicious abstraction that has done much to darken economic inquiry" (1879a, p. 385), and he urged the importance of historical studies for an understanding of the workings of an economic system. In particular, he stressed that competition had not brought about the equalization that theory assumed, and he documented his thesis by repeated citations of geographical differences in agricultural wages in England and Ireland.

Leslie was an acute critic and a careful observer who was quick to see facts that did not square with the theories of classical economics. He did little, however, to present an organized alternative approach or to consider what modification of theory might explain these individual situations. Leslie is sometimes referred to as spokesman of the historical approach to economics in England, but this does not mean that he was part of an organized movement like the German historical school. His wide-ranging criticism of classical economics and his emphasis on the importance of institutions have much in common with the work of Thorstein Veblen.

Numerous references to Leslie by neoclassical economists in the 1880s and 1890s—in particular Henry Sidgwick, John Neville Keynes, and Alfred Marshall—suggest that he had some influence in softening the rigidity of the deductive economics of the classical tradition then dominant in England. His essays on the land problem are still important for the history of the controversy over the economic difficulties of Ireland, and his stimulating criticisms of the purely deductive approach to economics have timeless relevance.

LEVASSEUR, ÉMILE

Émile Levasseur (1828–1911) was the father of modern economic history in France. He was born into a family of jewelers in Paris, and he himself worked at the jeweler's trade. It was this experience which aroused his interest in economic history. After the revolution of 1848, as he put it, "I became interested in political and social problems and, with the eagerness of youth I embraced the republican idea" (quoted in Hauser 1911, p. 88).

He received his secondary schooling in a Paris *lycée* and then attended the *École Normale Supérieure* and passed the *agrégation des lettres*; it may be worth noting that he never received a degree in history. He advanced rapidly in his academic career. Initially he taught rhetoric at Alençon and Besançon, but in 1868 he was asked to introduce economic history into the curriculum of the Collège de France, and in 1872 a chair of economic history and geography was created for him. In 1871 he succeeded Louis Wolowski at the Conservatoire des Arts et Métiers, and in the very same year he founded, with Émile Boutmy and Ernest Renan, the *École Libre des Sciences Politiques*, where he taught until his death.

Levasseur's concern with incorporating the material, concepts, and methods of the social and economic sciences into the study of history represented a break with the historical tradition of his time. And not only did he broaden the traditional

concept of history; he also brought history into the field of economics, following in the footsteps of the German historical school of economists in general and of Wilhelm Roscher in particular. Until the publication of Levasseur's *Recherches historiques sur le système de Law* (1854) and his *Histoire des classes ouvrières . . . avant 1789* (1859), political economy in France had been an abstract and speculative science; after Levasseur it became an area of historical research. He substituted historical criticism for theorizing and replaced abstractions with data derived from documents and the analysis of statistics.

To be sure, Levasseur made a fundamental distinction between what he called pure political economy, or economic science, and applied political economy, or "economic art"; his own sphere, economic history, was economic art. However, he saw the two aspects of political economy as inter-related: "Economic history is one of the branches of the history of civilization; it protects economic science from the errors of judgment that can result from abstraction, just as experience is a safeguard against the dangers of the mathematical method. In a way, economic history is political economy in action; it teaches, more or less clearly, the lesson of experience, and it is also ancillary to theory" (see Liesse 1914, pp. 348-349). Thus defined, political economy becomes a moral science, focused on man as the center of the whole economic process; he is both active principle and goal.

Of all the related sciences that Levasseur brought to bear on economic history, he singled out statistics as the most important. The publication of *La population française* (1889-1892) was, therefore, an even more important event in historiography than that of *Histoire des classes ouvrières*. For Levasseur, the object of statistics as a science was to make numerical data available to historians and economists. Indeed, he believed that statistics had become an indispensable tool for the historian.

Geography was another discipline Levasseur wished to see more closely connected with history. More than that, he made important contributions to the reorientation of the discipline and is considered one of the precursors of the great French geographers of the beginning of the twentieth century. In place of nomenclature and description, he substituted analysis of both present and future conditions. His 1879 report on the prospects of the proposed Panama Canal, made at the request of Ferdinand de Lesseps, is characteristic of this type of analysis: he calculated the traffic that could be expected and estimated the financial returns.

Finally, Levasseur considered what is now

called sociology to be indispensable to the historian.

Levasseur made the following programmatic statement about the ways in which the economic historian should proceed:

Economic history, using documents from the past, statistics, archival material, and the descriptions of contemporaries, etc. aims to explain either a single aspect of the economy of a particular nation, or successive manifestations of such a single aspect in the economies of several nations, or else to present a comprehensive picture of all aspects of a particular national economy. . . . Economic history enables us to observe and follow the progress of economic phenomena in their social milieu, and to determine as accurately as possible the causes and effects of each nation's economic activity. . . . It shows how economic development is an integral part of the general evolution of all societies. (1898, pp. 25-26)

Levasseur's conception of economic history was humanistic, rather than mechanistic. Thus, in a lecture at the Collège de France in 1898, he considered the reasons why once-flourishing empires declined. The soil and climate had remained the same. It was man who had changed. Either he no longer had the skill to raise the produce that had made him rich, or social conditions had diverted him from his original goal. Levasseur explored this humanistic and synthetic concept in the five volumes of his *Histoire des classes ouvrières et de l'industrie* (1867a), which is his masterpiece and which after a century remains in large part valid.

Levasseur's economic concepts are no longer accepted, and sociology and statistics have undergone rapid transformations since his death. However, Levasseur was an important innovator and one who laid the groundwork for, and to some degree directly inspired, such important scholars as François Simiand, Henri Hauser, Marc Bloch, and Ernest Labrousse. French economic historians today still revere him.

LÉVY-BRUHL, LUCIEN

Lucien Lévy-Bruhl (1857-1939), French anthropologist, was born in Paris. He received a *doctorat ès lettres* from the École Normale Supérieure, and entered upon a brilliant university career, which was crowned by his nomination to the chair of his-

tory of modern philosophy at the Sorbonne in 1904. His lectures there were the basis of several of his books, notably those on Jacobi (1894) and Auguste Comte (1900). His lasting contributions, however, are his book *Ethics and Moral Science* (1903) and especially the six volumes he devoted to the study of what he called the primitive mentality.

Lévy-Bruhl's work is highly original, and it is hard to define precisely the influences on his thinking. His stress on the role of the emotions in psychic life may have derived from his studies of Jacobi. In the sociological aspects of his thought he was influenced by the ideas of Émile Durkheim. Yet Lévy-Bruhl also rejected some of Durkheim's ideas and carried on spirited controversies with Durkheim, who then dominated the French sociological school. Lévy-Bruhl could not accept all the implications of Durkheimian rationalism, but he did learn much from Durkheim's *Rules of Sociological Method*. In general, one might say that Lévy-Bruhl was influenced more in a negative than in a positive sense. He was nobody's disciple; indeed, he often defined his thinking by contrasting it to that of others, for instance, to that of the theorists of animism (Frazer, Tylor, and Spencer). But he was not indifferent to criticisms made of his theories, especially the objections of such sociologists as Durkheim and Mauss or of an anthropologist like Evans-Pritchard. His responsiveness to these criticisms caused changes in the orientation of his thought. Three major stages may be distinguished in his intellectual development: the first was marked by his work on morality; the second by his theories on the primitive mentality; and the third by the revisions and changes that he himself made in these latter theories.

Moral philosophy. In *Ethics and Moral Science* Lévy-Bruhl began by showing that all theoretical moralities (whether of metaphysical or scientific origin) are doomed to failure, because theory can be applied only to what is, not to what ought to be. They suffer also from the fact that they fail to take into account the variation of human nature in various civilizations. Morals do vary with time and place, and Lévy-Bruhl advocated that they be studied objectively and that their laws be discovered. On the basis of such scientific knowledge, a rational art and rules of conduct may be set up that will be valid solely in a specified sociological situation rather than claiming the universal validity of the theoretical moralities. Thus, already in this book Lévy-Bruhl was making a direct attack on the postulate of the unity of human nature and laying the foundations of a relativistic and pluralistic sociology.

The theory of the primitive mentality. Lévy-Bruhl's pluralism led him to suppose that several types of mentality can exist among men, that is, that their methods of thinking may vary basically from one society to another. The surest way to prove this, he believed, was to begin by comparing the mentality of civilized man with the mentality furthest removed from it.

He therefore studied the mental functions in so-called primitives, collecting and classifying a large number of documents on this subject. His first conclusion was that the mentality of primitives and that of people living in modern Occidental civilization differ not in nuance or degree but rather in kind. The anthropologists of the English animist school had believed that primitive peoples think or reason in the same way as civilized ones, although they may reason from mistaken premises. For Lévy-Bruhl the primitive man's very reasoning processes differ from ours; the primitive mentality is not simply a rudimentary or pathological form of the civilized. What makes for these differences is not the thought of the individual but collective representations. Ideally, the social scientist would establish the particular collective psychology of each society. Instead, in order to describe the primitive mentality Lévy-Bruhl took his documentation from all preliterate societies.

To the objections of those, like Marcel Mauss, who argued that these societies are not all alike, Lévy-Bruhl answered that for his purpose it was enough that they all share a characteristic that distinguishes them from us. When Evans-Pritchard reproached him with taking his examples from the books of travelers or missionaries, whose observations had not been made in conformity with the best ethnographical methods, he replied that it sufficed for him if the mentality of the peoples studied had been well understood. Evans-Pritchard did get Lévy-Bruhl to admit that he sometimes made savages appear more irrational than they actually are; he maintained, however, that it was not his intention to give a complete description of the life of primitive peoples but to highlight the differences between their mentality and ours.

The collective representations of primitives, he asserted, are essentially mystical, since they imply belief in forces or influences that are imperceptible to the senses. Mysticism pervades all their perceptions. Further, the primitive mentality is not governed exclusively by our laws of logic. Although it is not generally opposed to these laws, it does not shrink from violating especially the law against contradiction. This is why Lévy-Bruhl designated it as prelogical. The connections made by the

primitive mind that fall outside of our principles of logic are governed by a principle that Lévy-Bruhl called the law of participation. According to this principle, a being or object can be both itself and at the same time something else. Participation cannot be explained by animism.

The conception of this mystical mentality based on participation led Lévy-Bruhl to more detailed analyses supported by a large number of concrete examples. He showed the effects of this mentality on the language of primitive peoples and on their way of conceiving the world. He described their occasionalist notion of causality and their way of looking at the human personality, distinguishing neither the human being (*l'être même*) from its "appurtenances," nor the body from the spirit or soul.

Between the primitive mind, which directly exhibits participation, and the civilized mind Lévy-Bruhl found intermediate stages in which participation can no longer be perceived directly but is represented or symbolized. He thus seems to have placed his dualism in an evolutionist perspective. But he took care to state that the mystical and prelogical mentality is never completely supplanted by the undisputed reign of logic. He held that in every human mind there is always some rational thought and some mystical thought. Reason alone cannot completely satisfy man. Lévy-Bruhl did not accept the charge that his was a doctrine of prelogicism. For him there are not two mentalities that exclude one another; prelogical thought is not a stage antedating logical thought. Thus, such philosophers as Émile Bréhier maintained that Lévy-Bruhl's theory is actually more structuralist than evolutionist. And the phenomenologist Van der Leeuw interpreted it as postulating the mystical mentality and the logical mentality as two permanent structures of the human mind. In primitive man, the first dominates the second; in civilized man, it is the contrary.

Revisions in the theory. Lévy-Bruhl's first books on mental functions in primitive societies provoked a vigorous reply from Durkheim in his *Elementary Forms of the Religious Life* of 1912. Many further criticisms appeared in 1926-1927, in particular those of Larguier des Bancels, Raoul Allier, and Olivier Leroy. Lévy-Bruhl examined these objections seriously and was led to sharpen and revise his thought. As a result between 1931 and 1938 he published three further books on the same subject. He now became more demanding as to the sources of his documentation, relying more frequently on the work of the best ethnographers. Also, without completely abandoning any of the basic concepts of his first analysis (mysticism, prelogical charac-

ter, participation, occasionalism), he inverted their order of importance, putting mysticism ahead of the prelogical character. And, above all, he introduced a new principle of explanation that tended to dominate all the others, which he called "the affective category of the supernatural." He still maintained, to be sure, that primitive peoples are sometimes insensitive to contradiction, but he strongly affirmed that "the fundamental structure of the human mind is the same everywhere." Primitive men have concepts, but their knowledge is not rationally classified and organized, which leaves the field clear for "mystical preconnections" when the emotional, affective element supplements logical generalization. This colors their entire thinking, since for them ordinary experience is pervaded by mystical experience; similarly, for them the supernatural world, although different from the natural world, is not separate from it, and they pass unaware from one to the other. The prelogical is therefore explained by the mystical and this in turn by the predominance of affectivity over reason. Indeed, affectivity gives a special tonality to primitive representations, and it thus has that element of generality that makes it a category of thought.

In his last works Lévy-Bruhl reduced the study of primitive mentality entirely to an analysis of the mystic experience and the affective category of the supernatural that characterizes and explains it. He showed how this experience of the supernatural emerges mainly in the face of the unusual. He devoted other chapters to the various representations and beliefs marked by this affective category, for example, occult influences, beings and objects that bring bad or good luck, various rituals, magic, revelations as to the secret nature of things and animals, dreams, visions, the presence of the dead, and all of mythology and the techniques for participating in the mythical world.

In these books Lévy-Bruhl was also concerned with transitions between the primitive and the modern mentalities. He found such transitions especially in the development of preresligion into elaborated religion, or of myth into tale and folklore; but at the same time he emphasized more and more that both mentalities persist.

Hence the theory that at the outset seemed to postulate a principle of radical difference between the thinking of primitive and civilized peoples became more flexible. This evolution continued in the notes that Lévy-Bruhl was writing toward the end of his life and that probably would have become a book had he lived longer. These notes were collected and published after his death in a small

book entitled *Les carnets de Lévy-Bruhl* (1949). In it he stated that he was prepared to give up the term "prelogical," and he even questioned the specificity of the characteristics he had attributed to the primitive mentality.

Influence of Lévy-Bruhl. In addition to the phenomenological and structuralist extensions of Lévy-Bruhl's theory, mentioned above, the important influence it has had on the Jungian psychoanalysts should be pointed out: Aldrich (1931) has related the primitive mind to the archetypes of the unconscious. As for the fundamentals of the doctrine, however, few contemporary authors seem to accept a difference in kind between the primitive and the civilized mind. Lévy-Bruhl himself was on the point of giving it up, as may be seen in his posthumously published notebooks. But his analyses of participation play an important part in the thought of many philosophers and sociologists, for example, Przyłuski (1940) and Roger Bastide (1953). Again, the advocates of a pluralist sociology, like Georges Gurvich, applaud Lévy-Bruhl's undermining of the classical unitary conception of the universality of modes of thinking. Lévy-Bruhl's doctrine may have few faithful disciples, but at least it compelled anthropologists to reflect on certain problems and in that sense gave a new direction to the study of primitive peoples.

JEAN CAZENEUVE

LEWIN, KURT

Kurt Lewin (1890-1947) was born in Mogilno, Prussia. After studying at the universities of Freiburg and Munich, he completed his doctorate in philosophy at the University of Berlin in 1914. He taught in Berlin from 1921 to 1933, at which time he left Germany. In the United States he was a visiting professor at Stanford and at Cornell before becoming professor of child psychology in the Child Welfare Research Station of the State University of Iowa in 1935. In 1945 he left Iowa to found the Research Center for Group Dynamics at the Massachusetts Institute of Technology. He also served as a visiting professor at the University of California in Berkeley and at Harvard.

During his thirty years of scientific work, Lewin's theoretical interests and the focuses of his research shifted several times. At first he was concerned with the study and analysis of the cognitive processes of learning and perception; with the dynamics of individual motivation and emotion; and with the interpersonal processes of reward and punishment, conflict, and social influence. In his next phase, he conducted and stimulated research on group phenomena such as leadership, social cli-

mate, group standards, and values. Finally, he was led to an examination of the social restraints imposed on groups by technology, economics, law, and politics. Although his interests changed and developed, he nevertheless carefully adhered to a central theoretical tenet: that to represent and interpret faithfully the complexity of concrete reality situations requires continual crossing of the traditional boundaries of the social sciences, rather than a progressive narrowing of attention to a limited number of variables.

The theory that requires this interdisciplinary approach to psychological and social reality has at various times been referred to, by Lewin himself and by others, as "dynamic theory," "topological psychology," and "field theory." Field theory was Lewin's final preference. Briefly stated, it holds that events are determined by forces acting on them in an immediate field rather than by forces acting at a distance. Field theory may be characterized as a method of analyzing causal relations and building scientific constructs, that is, a theory about theory building, or a metatheory. At the same time, Lewin's field theory is a set of constructs, developed through empirical research, for describing and interpreting psychological and social phenomena.

Field theory as metatheory. The major tenets of field theory as metatheory for social science have been identified by Cartwright (1959, p. 7).

(1) The full empirical reality of human experience and behavior—not just certain abstract aspects that are most accessible or easy to manipulate—must be comprehended in a scientific manner. The observation of behavior in a real-life setting (what has been called naturalistic observation) and phenomenological analysis are procedures that may prevent scientific formalization from focusing on trivial aspects of human behavior.

(2) The language of concepts that is developed must be "two-faced," providing both a rigorous terminology for describing the behavioral events of the real world and a set of theoretical constructs that can be related to each other logically in the formulation of lawful regularities about the causation of behavioral events.

(3) The concepts must "fit" the nature of psychological phenomena, which they will not do if they are simply borrowed from physical or biological science. Presuppositions about the ultimate unity of science should not be allowed to distort the development of concepts that are intended to describe psychological phenomena (emotions, hopes, fears, illusions) rather than biological or physical processes.

(4) *Lewin's principle of concreteness* states that effects "can be produced only by what is 'concrete,' i.e., by something that has the position of an individual fact which exists at a certain moment" (1936, p. 32). From this important principle Lewin derived several of his basic ideas: that every behavioral event must be viewed as caused by several interdependent features of the total concrete situation of that moment; that the dynamics of a behavioral event cannot be adequately comprehended by the specialized concepts of a particular discipline or scientific specialty, for example, cognition, learning, economics, or political science; that the "life space" or concrete field of all coexisting psychological facts is quite different from the quantified dimensions of that situation; that causation is a contemporary process—"Since neither the past nor the future exists at the present moment it cannot have effects at the present" (*ibid.*, p. 35).

(5) Mathematics provides basic tools for developing a formal systematic theory of psychological processes, but this does not mean that all phenomena can be treated quantitatively. Non-Euclidean geometry seemed to Lewin the most appropriate mathematical tool for treating many empirical aspects of human behavior in terms of psychological space.

(6) Basic research that is generated by the need to develop field theoretical concepts should be of great practical value in the world of action. To Lewin this meant that there "is nothing as practical as a good theory." He demonstrated this again and again in his own contributions to the understanding of many critical social problems, such as autocracy, self-hatred, scapegoating, intergroup conflict, industrial inefficiency, conservative food habits, and child rearing. [See PREJUDICE.]

Experimental research. In his search for a comprehensive conceptual grasp of significant psychological events and processes Lewin instigated and led many research programs. Often they were carried on by his students after he himself had turned his attention to new problems.

His first research sequence began with an experimental critique of the work of Ach (1910) on "associative bonds" in the process of remembering. Lewin moved beyond structural concepts of remembering to such notions as intention to recall and expectation about events. Basic work was done by Ovsiankina (1928) and Zeigarnik (1927), who demonstrated experimentally that the tendency to recall interrupted tasks is stronger than the tendency to recall completed tasks and that there are forces acting toward resuming and completing interrupted activities.

This work on psychological interruption and on the forces acting toward resumption and completion led directly to another program of research that represents an early experimental investigation of motivational concepts. The research sought to discover whether the completion of a task different from the interrupted one can reduce the tendency to resume the interrupted one. In other words, can one task have substitute value for another? Lewin's students Lissner (1933) and Mahler (1933) demonstrated that tasks of different degrees of similarity and different degrees of reality have different types of substitute value. An important series of studies by Adler (1939), Cartwright (1942), and Sliosberg (1934) further developed this area of inquiry.

Lewin's interest in the internal dynamics of motivation led him to initiate another series of studies on the psychological process of satiation. Karsten (1928) and other students (Freund 1930; Kounin 1941; Seashore & Bavelas 1942) discovered that the time it takes to become satiated with a task depends on the over-all meaning context of the activity, on ego involvement in the activity, on the physiological state of the person, and on the degree of rigidity of interpersonal psychological systems.

Another important series of studies of motivational dynamics dealt with frustration and regression. Again, Lewin's plan of research was primarily carried out by others. Dembo's initial work in Berlin (1931) consisted of careful observational studies of the symptoms of emotional tension as contrasted to the symptoms of task- or problem-solving tension that occurred when subjects were assigned impossible tasks. The symptoms observed included anger, aggression, regression, substitution, and flight from reality. Later studies by Barker, Dembo, and Lewin (1941) and by Wright (1942) established important connections between frustration and intellectual regression as measured by the developmental level of play activity before and after frustration situations.

Dembo (1931) and Hoppe (1931) did valuable research on the concept of level of aspiration, and again other research developed from it. After Jerome Frank, one of Lewin's students, presented a summary in English of the German research (1935a; 1935b), a flood of studies by American investigators followed. The early research indicated that the experience of success or failure depends to a very significant degree upon the person's aspiration rather than upon some objective standard of performance. There was also clear evidence that the motivation for success or achievement of in-

dividuals leads them to set levels of aspiration that do not guarantee easy success. This line of inquiry has been the springboard for much of the current advanced theoretical work on social comparison processes, self-evaluation, and discrepancies between ideal self and actual self. [See *ACHIEVEMENT MOTIVATION*.]

The phenomena of decision making and conflict resolution were the focuses of another important series of investigations by Lewin and his students. These inquiries demonstrate the effect on decision making of the strength of the valences of the alternatives, the reality level of the choice situation, the difference in a choice between negative and positive alternatives, and attitudes of cautiousness and risk taking.

As Lewin's interests changed from individual to social psychology, his approach to decision making and conflict also changed. His famous series of studies of group decision making (1953) demonstrates the influence on individual behavior of participation in group discussions and decisions. Group discussion affects such phenomena as parental behavior, eating habits, and amount of effort on the production line. Later work on patterns of intergroup conflict derived from this work on individual decision making.

As he moved into social psychology, Lewin's research interests focused on the phenomena of social perception, social values, social influence, cooperation, and competition. In all these areas he instigated important research. His students demonstrated experimentally that the expectation or perception that another person is "warm" or "cold," high or low in power, or an insider or outsider greatly influences interpersonal attitudes and behavior (Kelley 1950; Pepitone 1950; Thibaut & Riecken 1955). [See *PERCEPTION, articles on PERSON PERCEPTION and SOCIAL PERCEPTION*.]

His move from Germany to the United States stimulated Lewin's interest in the comparative analysis of personal values as they relate to cultural differences and social norms. Several of Lewin's papers ([1935-1946] 1948, pp. 3-68) deal with the development of a definition of values and with approaches to change in cultural values. This was perhaps the beginning of his focus on the theory of planned change and social action, which became increasingly important in the later years of his career. His work on values moved from methodological work on the content of values (as developed in Kalthorn 1944; White 1951) to work on the development of the value of "fairness," which he conducted by means of experimental situations with children of different ages, and then

to an important series of studies on the development and functioning of group standards or group norms. The experimental field studies of the influence of group standards on work output in a factory (Coch & French 1948) and on behavior of residents in a housing project (Festinger et al. 1950) led to a basic theoretical paper in 1947 by Lewin (see in [1939-1947] 1963, pp. 188-237) on the quasi-stationary equilibrium as a tool for conceptual analysis of the field of forces determining behavior in a given social setting and situation. [See *MORAL DEVELOPMENT*.]

Perhaps Lewin's best-known contributions to social psychology and group dynamics are those focusing on authority and social influence. Initially, a series of children's groups were studied to see what effect different styles of leadership might have on the social-emotional atmosphere of a group, on its work productivity, and on the personal adaptation of members. There followed basic work on social influence, with laboratory studies of status hierarchy and communications channels; field studies of behavioral contagion and influence structures; and studies of the patterns and bases of influence in military units and in the working relations among the members of professional teams, such as those composed of psychiatrists, clinical psychologists, or social workers. [See *LEADERSHIP*.]

In the later years of his career, Lewin and his co-workers became interested in the problem of what they called psychological ecology. Thus, in his work on the maintenance and change of food habits (1943), Lewin constructed a theory of social channels and "gatekeepers" to account for the ecological processes by which particular foods reach the table and come in contact with the consumer. He showed that a number of cultural, economic, and technological factors combined to influence this series of decisions. This approach has been greatly developed and extended by Lewin's student and co-worker Barker, in his series of field studies of the psychological ecology of children and adults in a number of communities and a variety of social settings (Barker & Wright 1954).

Major concepts. In all his work, Lewin maintained an active interplay between the construction of theory and the concrete analysis of human behavior in all its complexity. It is possible here to indicate only briefly some of the concepts that became important in Lewin's comprehensive conceptual system. Probably the most widely known Lewinian concept is that of *psychological life space*. This fundamental notion refers to the totality of events or facts that determines the be-

havior of an individual at a given time. It is related to the basic tenet that causation is a contemporary process, and it has, therefore, created much active controversy in the field of psychotherapy. Defending the importance of this concept, one psychoanalyst (Ezriel 1956, p. 32) has asserted that the unconscious structures the analyst uncovers in working with a patient are *active in the present* and are not necessarily replicas of past realities and reactions.

The life space includes two major components: the person and the psychological environment. The latter is conceived to be the environment as it exists for the individual. Lewin assumed that an understanding of the interaction between the person and the psychological environment would permit the understanding and prediction of the person's behavior.

The concepts that Lewin developed to deal with the psychological and social processes of the life space can be classified as *structural* concepts, having to do with the arrangement and relationship of the parts of the life space, and *dynamic* concepts, dealing with tendencies toward change or resisting change. The basic structures of the life space are region and boundary, and derived from these are degree of differentiation, centrality, path, and psychological distance. The principal dynamic processes are interdependence, tension, force, field of forces, equilibrium, and power. Lewin also introduced two dimensions of the life space: a vertical dimension of degrees or levels of reality and a horizontal dimension of time perspective. Lewin's studies demonstrated that psychological processes vary with different levels of reality: the processes involved in assessing facts or expectations are different from those involved in fantasies or wishes. The use of the concept of time perspective was related to Lewin's field-theoretical stress on the interpretation and prediction of behavior in ahistorical terms.

When he first made contributions to social psychology, Lewin was content to treat the facts of interpersonal relations as social facts in the life space of each individual. For example, the fact of group membership and its implications for behavior then seemed quite satisfactorily represented as regions in the life space of the person. But as he added such new problems as group goals, group decision making, and group problem solving, it became necessary to relate life spaces to one another, that is, to construct a *social space* or a social field in which social, economic, political, and physical facts have objective, or at least intersubjective, reality, rather than only individual

psychological reality. In some of his final papers ([1939-1947] 1963, pp. 170-237), Lewin was beginning to grapple with the challenging problems of defining social space and social field-theory and of relating these concepts to those of psychological space. He was indicating some of the ways in which the behavioral sciences might go beyond empirical unity to the achievement of conceptual unity.

Social action and social problem solving. Lewin had a deep sensitivity to social problems and a commitment to use his resources as a social scientist to do something about them. Thus, in the early 1940s, he drew a triangle to represent the interdependence of research, training (or education), and action in producing social change. He saw every practical problem as requiring basic conceptual analysis, research, and a "change experiment." The concept of action-research as a method of planned social change was developed and clarified in the period when he was helping found the Commission on Community Interrelations of the American Jewish Congress and establishing the Research Center for Group Dynamics at MIT.

Lewin may well have been a bit optimistic when he asserted in 1945 that "leading practitioners" in government, agriculture, industry, education, and community life seemed to have an increasing awareness of the need for a "scientific level of understanding" and that they seemed to accept the dictum that "nothing is as practical as a good theory." Yet the success of the National Training Laboratories, which he helped establish in 1946 and 1947, does seem to vindicate his optimism. First held at Bethel, Maine, the summer after Lewin's death, these sessions have since expanded into a nationwide network serving the needs of professional men. They provide a link between these professional men and the resources of the behavioral sciences and the growing technology of re-education of attitudes, values, and behavior.

Persisting influence. Current research directly derived from Lewin's work is being carried on by Cartwright and his colleagues, who are working on the development and use of mathematical concepts that are coordinated with life-space phenomena; at the Research Center for Group Dynamics at the University of Michigan (it was founded by Lewin at MIT and moved to Michigan after his death) and at university centers founded by some of his students, for example, by Festinger, Schachter, Deutsch, Thibaut, and Kelley; by Barker and his colleagues, working on psychological ecology; by French, Bavelas, Marrow,

Cook, and others, who are coordinating organizational field experiments; and by Lippitt and his colleagues at the Center for Research on Utilization of Scientific Knowledge, the title of which is a key to its activities.

LEXIS, WILHELM

Wilhelm Lexis (1837-1914), a German statistician and economist, made major contributions to the theory of statistics and its application, particularly in population research and economic time series. As a mathematician Lexis was deeply skeptical about the state of mathematical economics in his time. His criticism of certain contemporary work in mathematical economics led him to some fundamental observations on economic events and their interdependence.

Lexis was born in Eschweiler, near Aachen, Germany. His studies were widespread, and his interests ranged from law to the natural sciences and mathematics. He graduated from the University of Bonn in 1859, having written a thesis on analytical mechanics; he also obtained a degree in mathematics. For some time he did research in Bunsen's chemical laboratories in Heidelberg. In 1861, Lexis went to Paris to study the social sciences, and his studies led to his first major publication (1870), a treatise on French export policies. This work displays the feature that characterizes his later economic writings: a skepticism toward "pure economics" and toward the application of supposedly descriptive mathematical models which have no reference to economic reality. Even in this early work he insisted that economic theory should be founded on quantitative economic data. In Lexis' view an elaborate general economic equilibrium analysis, whose main problem was to match the unknowns with an equal number of equations, could make no contribution to the understanding or solution of economic problems and therefore should not be taken too seriously. He was one of a number of mathematically trained students of economics who, in the second half of the nineteenth century, became alienated from that discipline;

another, more famous one was Max Planck, who, after attempting to read Marshall's work, threw it away and changed his course of study for good (see Schumpeter 1954, pp. 957-958).

Lexis was appointed to the University of Strassburg in 1872. While there, he wrote his introduction to the theory of population (1875). From Strassburg he went to Dorpat in 1874, as professor of geography, ethnology, and statistics, and then to Freiburg in 1876, as professor of economics. His major contributions to statistics were made while he was at Freiburg (1876; 1877; 1879a), and he also published papers on economics at this time (1879b; 1881; 1882a; 1882b). After an interlude at the University of Breslau from 1884 to 1887, he was appointed professor of political science at the University of Göttingen.

Lexis' activities in his later years were remarkably diverse. An editor of the *Handwörterbuch der Staatswissenschaften*, the major German economic encyclopedia, he was also an active contributor, and he was director of the first institute of actuarial sciences in Germany. In the 1890s he published and edited several volumes pertaining to education, particularly to the university system (1893; 1901; 1902; 1904a; 1904b). Lexis' works on population research, economics, and statistics during the subsequent decade bring together and refine some of his earlier arguments (see 1903; 1906a; 1906b; 1908; 1914). He died in Göttingen during the very first days of World War I.

Statistics

Lexis' major contributions were in statistics. His statistical work originated in problems he encountered in population research (1875; 1879b; 1891; 1903), sociology (1877), and economics (1870; 1879a; 1908; 1914). In connection with his studies of social mass phenomena (1877) and the time series encountered in several of the social sciences (1879b), Lexis came upon problems concerning statistical homogeneity which apparently had been neglected up to then, although, as Bortkiewicz pointed out (1918), Dormoy (1874; 1878) developed similar ideas at about the same time. (Other possible forerunners of Lexis were Bienaymé [1855], Cournot [1843], and R. Campbell [1859].) Lexis credited Dormoy with having anticipated some of his ideas; nevertheless, it was Lexis who more or less independently gave a new direction to the analysis of statistical series and led statisticians in the shift of emphasis from the purely mathematical approach, with which Laplace is associated, to an empirical or inductive approach (see Keynes 1921, pp. 392 ff.). He also initiated

the analysis of dispersion and variance in his attempts to develop statistics with which to evaluate qualitative changes in populations over time (see Keynes 1921; Pólya 1919).

Lexis showed that in the universe of social mass phenomena the conditions of statistical homogeneity (random sampling from a stable distribution) are seldom, if ever, fulfilled (1877; 1879a; 1879b). The underlying probability structure may well differ from one part of the sample to another because of special circumstances related to dispersion in space, time, or other factors. A universe in which individual samples are drawn from potentially different populations is now known as a *Lexis universe* (see, for example, Herdan 1966). To some extent Lexis' work was a reaction to the uncritical assumptions of homogeneity made in statistical work before his time—for instance, by Quetelet. As Keynes (1921) pointed out, Quetelet and others simply asserted, with little evidence, the probabilistic stability from year to year of various social statistics.

Lexis' work centered on the dispersion of observations around their local means and on the behavior of the means and dispersions over time. He devised statistics to measure the degree of stability of such time series and arrived at the useful generalization that these statistics would either confirm statistical homogeneity, indicating a *Bernoulli series*, or diverge from it, indicating a *Poisson series* or a *Lexis series*. (This terminology was developed by C. V. L. Charlier; see A. Fisher 1915, p. 117).

Lexis considered only dichotomous variates (male–female, living–dead, etc.), but the argument he advanced holds equally for numerical variates in the ordinary sense (see also Pólya 1919). In the following, Lexis' ideas are given in a generalized form.

Let x_{ij} ($i = 1, \dots, n$, $j = 1, \dots, m$) be a set of n samples with m observations each, and let the arithmetic mean of the x_{ij} in sample i be \bar{x}_i and the arithmetic mean of the x_{ij} over all n samples be \bar{x} . Similarly, let $a_{ij} = E(x_{ij})$, the expectation of x_{ij} , so that $\bar{a}_i = E(\bar{x}_i)$ and $\bar{a} = E(\bar{x})$. Lexis considered the following quadratic forms which measure dispersion in three different senses:

$$s_w^2 = \frac{1}{nm} \sum_i \sum_j (x_{ij} - \bar{x})^2,$$

$$s_b^2 = \frac{1}{n} \sum_i (\bar{x}_i - \bar{x})^2,$$

$$s^2 = \frac{1}{nm} \sum_i \sum_j (x_{ij} - \bar{x})^2,$$

where s_b^2 has rank (degrees of freedom) $r_b = n - 1$, s_w^2 has rank $r_w = n(m - 1)$, and s^2 has rank $r = r_b + r_w = nm - 1$. (The subscripts "w" and "b" are used to indicate that s_w^2 comprises within sample dispersion and s_b^2 between sample dispersion.) Furthermore,

$$s^2 = s_b^2 + s_w^2.$$

If the n samples of m objects each are drawn at random from the same population, then the expected value of each observation equals the expected value of the sample mean and the expected value of the mean of all observations, that is,

$$a_{ij} = \bar{a}_i = \bar{a},$$

and statistical homogeneity is present. Repeated independent measurements of a distance and $n \times m$ drawings of balls from an urn with each ball returned after it is drawn are examples of such series. In this case the three quadratic forms, multiplied by appropriate constants, have the same expectations. Specifically, when statistical homogeneity holds,

$$E\left(\frac{n}{r} s^2\right) = E\left(\frac{n}{r_b} s_b^2\right) = E\left(\frac{n}{r_w} s_w^2\right),$$

and the common value is $1/m$ times the variance of the underlying population. A set of samples drawn under such conditions is known as a *Bernoulli series* (see, e.g., A. Fisher 1915).

It may, however, be the case that statistical homogeneity holds within the samples ($a_{i1} = a_{i2} = \dots = a_{im}$) but not between samples—that is, the n samples may be random samples from different populations. In this case a Lexis series is generated (a supernormal series, in Lexis' terminology). Such a series is expected when, for example, each set of balls (one sample) is drawn from a different urn. Other examples of such series explain further the importance of the Lexis series: m observations made at time t_0 , another m observations made at time t_1 , and so forth, up to t_n , will give rise to a *time series* of $m \times n$ observations, where the i th sample (covering one period, t_i) may well come from a single population but where between different periods such changes occurred that statistical homogeneity is no longer preserved—that is, the samples come from different populations.

Similarly, social or economic samples of m observations drawn from n different geographical regions (nations) are likely to come from different statistical populations, although in each region (nation) the m observations of the sample come from the same distribution (*interregional series*, in-

ternational series). In short, if the over-all dispersion is caused not only by chance variations about a constant but also by trends and other systematic factors varying between samples, then a Lexis series will be generated. (A comprehensive and elementary treatment of Lexis series is given in Pólya 1919.)

We expect in this case that the variance between the samples will contribute relatively more to the over-all variance of the $m \times n$ observations than will the variance within the samples and that the expected value of an observation will equal the sample mean, whereas the sample mean is expected to differ from the mean of all observations. Further, although $a_{ij} = \bar{a}_i$, $\bar{a}_i \neq \bar{a}$ for at least some i and

$$E\left(\frac{n}{r_i} s_{ir}^2\right) < E\left(\frac{n}{r} s^2\right) < E\left(\frac{n}{r_b} s_b^2\right).$$

Statistical homogeneity is not preserved.

Much less realistic, but a formal complement to the Bernoulli and Lexis series, is the Poisson series (a subnormal series, in Lexis' terminology). The Poisson model was developed as one that would generate higher within sample than between sample variability. In this case the j th observation of each sample is drawn from a fixed population, but the populations differ according to j . In short, $a_{ij} = a_{2j} = \dots = a_{nj}$, but for a fixed i the a_{ij} are not all equal. Hence $\bar{a}_i = \bar{a}$, and there is no between sample variability coming from the a 's. It follows that

$$E\left(\frac{n}{r_b} s_b^2\right) < E\left(\frac{n}{r} s^2\right) < E\left(\frac{n}{r_w} s_w^2\right).$$

Other kinds of models leading to subnormal dispersion have also been considered.

Lexis proposed a statistic, based on the above quadratic forms, to describe the extent to which a given series is homogeneous, supernormal, or subnormal. The statistic, called the Lexis quotient, is

$$L = \frac{s_b^2/r_b}{s^2/r},$$

a monotone increasing function of another statistic, $(s_b^2/r_b)/(s_w^2/r_w)$, which might be used alternatively. A. A. Chuprov showed later (1922) that in the case of statistical homogeneity, $E(L) = 1$ and the variance of L is approximately $2/(n-1)$.

A further elaboration of this leads to significance tests. A first step in that direction is made by adding to and subtracting from the expected value of L its standard error, obtaining $1 \pm \sqrt{2/(n-1)}$. If L lies within the boundaries thus calculated, one may conclude with confidence of approximately two out of three that the statistical mass is homo-

neous; if L is significantly larger than 1, one may conclude that the series was drawn from a Lexis universe; and if L is significantly smaller than 1, one may conclude that the series is Poisson.

The relevance and connections of the Lexis series and Lexis' L to the analysis of variance and the chi-square distribution were later shown by many authors. The formal connection between L and the χ^2 statistic of Pearson was elaborated by R. A. Fisher. Fisher showed that in the case of a $2 \times n$ classification the χ^2 statistic is just nL . [See COUNTED DATA; see also R. A. Fisher 1928; Gebelein & Heite 1951.]

The relation of the L -statistic to the F -statistic is very direct, and we may say that Lexis anticipated the F -statistic (see Coolidge 1921; Rietz 1932; Geiringer 1942a; 1942b; Gini 1956; Herdan 1966). Whereas in L one compares the variance between the samples to the variance of all $n \times m$ observations, that is,

$$L = \frac{s_b^2/r_b}{s^2/r},$$

in the F -statistic one compares the variance between the samples to the variance within the samples, that is,

$$F = \frac{s_b^2/r_b}{s_w^2/r_w}.$$

Furthermore,

$$L \geq 1 \quad \text{if and only if} \quad F \geq 1.$$

This concurrence is based on the previously stated equality

$$s^2 = s_b^2 + s_w^2.$$

Although the asymptotic distribution of the F -statistic as $m \rightarrow \infty$ was established by R. A. Fisher (1925, p. 97) and by W. G. Cochran (1934, p. 178) and generalized by M. G. Madow (1940), the same distribution was established for Lexis' L as early as 1876 by F. R. Helmert, using the method of characteristic functions.

Bortkiewicz extended the application of Lexis' theory of dispersion, and Chuprov (1922) extended Lexis' theory and gave it the most comprehensive treatment. Others influenced by Lexis were J. von Kries, H. Westergaard, and F. Y. Edgeworth, the only Anglo-American scholar closely familiar with statistical work on the Continent at that time (see Keynes 1921).

Economics

Lexis' contributions to economic theory were less appreciated than were his contributions to sta-

tistics; many economists, including Schumpeter, largely ignored them. Such a negative assessment of Lexis' work proves to be not entirely justified after closer examination of the reasons that led him to criticize certain aspects of the mathematical and "pure" economics of his contemporaries. His main contribution was a valid criticism of the work done at his time, particularly that of the Austrian school and the Lausanne school. His criticism was informed in part by the outlook of the historical school, which was prevalent in Germany, and accordingly he believed that it was necessary to incorporate in any theory of value and demand the element of time as well as the phenomenon of the recurrence of wants.

Lexis accepted Gossen's analysis of human behavior because Gossen appreciated all the shortcomings of any such theory. The criticisms Lexis made of the Austrian school seem contradictory but are only superficially so: he deplored the lack of mathematics in the work of some authors, especially Carl Menger, and found fault with the application of inappropriate mathematics in the work of others, especially Auspitz and Lieben.

Lexis regarded the concept of utility as being rather vague, since utility cannot be measured. He argued that to say that the utility of a good (set of goods) is equal to, larger than, or less than the utility of some other good permits a partial or complete preordering of utilities. Complementarity and substitution effects imply, however, subadditivity and superadditivity of utilities, which render futile any attempt to aggregate utilities and demand correspondences. Lexis questioned the convexity and continuity assumptions of preference orderings.

The controversy then raging over how to determine total utility given the marginal utility correspondences (a controversy between E. von Böhm-Bawerk and F. von Wieser) was correctly interpreted by Lexis and led him to a discussion of Gossen's other laws, most notably the equalization of marginal utilities. Any such theorem, he believed, must be hedged by a number of qualifications; it is particularly important to consider the time element connected with demand and consumption. Want and satisfaction are both felt and exercised over time. At one and the same time only a limited set of wants can be satisfied. One can eat, drink, sleep, and work, but these activities are to some extent mutually exclusive. Thus, the individual has to decide what sequence to follow in satisfying his set of wants. This sequence will be determined, according to Lexis, by the intensity of wants and by their periodicity, the most fundamen-

tal rhythms being the day, the year, and one lifetime. The demand of an individual will be classified and exercised accordingly. Intensive wants will be satisfied first, on a daily, yearly, or other basis, depending on the periodicity of recurrence of wants. Other, less intensive wants will be satisfied after full satisfaction of the intensive wants has been achieved. The implications are far-reaching but perhaps misleading; they have not been accepted by subsequent economists. Individual demand correspondences have to be defined by the period to which they relate, which in turn requires a reformulation of the theory of demand and implies the necessity of defining the demand for (consumption of) each good at different times as quantitatively different. This entails no theoretical difficulties in a general mathematical equilibrium analysis, but it does prevent the theory from having any operational value.

The concept of preferential ordering over time induced Lexis to observe that certain more intensive wants will be saturated whereas other, less intensive wants will be satisfied partially, implying satisfaction of zero marginal utility for the first set of wants and some positive marginal utility for the second. Lexis supported this conclusion by referring to economic reality. However, his statement about the equalization of marginal utilities turns out ultimately to be incorrect if we allow for errors of judgment, evaluations of uncertainties and risks, and diversity of attributes of each good for any individual.

Thus, Lexis' skepticism about the potential of the marginal utility theory in economics was based on the difficulty of measuring utility, the existence of subadditivities and superadditivities in utility correspondences, and the impossibility of aggregating individual preferences. The introduction of the time element into the theory of value and demand adds interesting arguments to general equilibrium analysis which imply, according to Lexis, obvious refutations of the equalization of marginal utilities. As a consequence of his skepticism, Lexis turned, in the rest of his economic work, to a rather dry description of economic events, which failed to be attractive to more speculative minds.

LIBERALISM

Liberalism is the belief in and commitment to a set of methods and policies that have as their common aim greater freedom for individual men. Early liberalism was identified with political parties or social classes and often with specific programs. Today, although some parties in Europe, Great Britain, and elsewhere bear the title Liberal, in contemporary usage the term "liberalism" refers to a system of thought and practice that is less specific than a philosophical doctrine and more inclusive than party principle. Liberalism is also too ecumenical and too pluralistic to be called, prop-

erly, an ideology. Contemporary liberalism is the product of centuries of development and of attitudes and responses widely shared among individuals. It can be described as: (1) a valuing of the free expression of individual personality; (2) a belief in men's ability to make that expression valuable to themselves and to society; and (3) the upholding of those institutions and policies that protect and foster both free expression and confidence in that freedom.

The term "liberal" probably first acquired its modern political connotation from the Liberales, a Spanish party that supported for Spain a version of the French constitution of 1791. As a coherent system of ideals and practical goals, however, liberalism first developed in England in the seventeenth and eighteenth centuries. Thereafter, liberal parties and liberal views, developing independently or derived from the English model, appeared in Europe, several British colonies, and elsewhere in the world.

Liberal thought and practice have stressed two primary themes. One is the dislike for arbitrary authority, complemented by the aim of replacing that authority by other forms of social practice. A second theme is the free expression of individual personality. Liberal movements and liberal thought have usually emphasized one theme more than the other, though seldom one to the virtual exclusion of the other. Much of liberal political and social theory has, in fact, been devoted to reconciling these two aims, especially with respect to their philosophical and practical implications.

Early liberalism emphasized freedom from arbitrary authority. One mode of attack was the assertion of free conscience and the demand for religious tolerance. Liberals have often been non-conformists in religion, secularists, skeptics, and even antireligious. In place of traditional authority they have supported the authority of reason and of demonstrated, rather than revealed, truth. Liberalism has stressed also the desirability of impersonal social and political controls: the rule of law and the market. Liberals have usually been individualists and pluralists and have supported local and group liberties and the methods of consent and persuasion.

Also vital to liberalism has been the goal of an active freedom, the ideal that the individual has the opportunity and the capacity for free expression. To this end, liberals have supported a more equal distribution of liberty, the abolition of monopolies, the destruction of aristocratic privilege, and a law that was general and founded upon rational principles. Liberals have argued also for

the expansion of opportunity, including state intervention to equalize and increase the opportunities open to individuals. For all these reasons, liberalism has usually been "progressive," i.e., concerned with economic and social progress and favorable to science, technology, and pragmatic experimentalism.

The two most important objectives of liberalism—noninterference and enfranchisement—support each other but also conflict. The first objective, pursued to an extreme, would leave the individual at the mercy of nature, society, and group and economic power. The second, followed alone, leads ultimately to statism and technocracy. Liberalism is neither of the extremes. It is a reconciliation of the two goals, with the relation between them determined by the needs of a society and the means available to it. Thus, liberalism does not, in fact, include such disparate figures as Rexford G. Tugwell, John Dewey, and Ludwig von Mises. Each is in part illiberal. Liberalism requires a rational and conscientious reconciliation of two essential goals.

The heritage of liberalism

Liberalism, in both its classical and its more contemporary, or "revisionist," forms, is essentially a modern phenomenon. It is the heir of a rich tradition. Liberty, constitutionalism, and toleration were known to the ancient world, and the Western liberalism of England, Europe, and America is the beneficiary of several religious traditions, of Greek philosophy and literature, of Roman law and constitutionalism. In the ancient world, however, liberty was closely associated with religion, ethnic culture, and citizenship. Liberalism itself did not exist as a separate and self-sustaining tradition. Moreover, the line of descent from ancient to modern liberty is not a direct one. The liberalism that developed in England and Europe in the eighteenth and nineteenth centuries was, at that time, a unique occurrence, resulting from the convergence of social and political tendencies peculiar to a specific time and environment.

Liberalism benefited from medieval constitutionalism and from the religious traditions of the church and Western Christianity. English liberalism, because of the common law, the parliamentary tradition, and the peaceful character of the English Reformation, drew much from this background, a fact illustrated by the works of John Fortescue, Richard Hooker, and Edward Coke. On the Continent the same materials proved less usable, but they served in a limited way to legitimate ancient liberties, a measure of toleration, and the rule of law.

The Renaissance and the Reformation were important in fostering liberalism, especially through the contribution they made to individualism. The Protestant doctrine that each believer could communicate directly with God, without dependence upon priest or churchly hierarchy, was an important anti-institutional influence and therefore favorable to individualism. Ideals of personal sanctification and inwardness of moral life that earlier had been restricted to orders of monks, knights, and burghers were democratized during the fifteenth and sixteenth centuries. In addition, the Reformation and the Counter Reformation, by stressing internal energy, individual responsibility, and the need for reconstructing the worldly order, greatly stimulated individualism, despite the intentions of Luther and Calvin or St. Ignatius and Pope Paul III.

Political changes, especially during and after the Reformation, contributed ultimately to the rise of liberalism. Wars decimated nobilities, broke down settled relations between lord and commoner, engaged new groups in collective activity. The domestic and international policies of monarchs brought to prominence bureaucrats of common or semi-noble status, lawyers, town merchants, military adventurers, and scholars and scientists. The new nation-states fostered changes in law, in the economy, and in personal relations that increased commerce and the circulation of money, and the numbers of merchants, masters, and artificers. Not to be ignored is the further fact that many of these political changes entailed taxation, intervention, oppression, and suppression, which were important issues in later constitutional struggles and liberal protests.

From the policies of modern states, from economic change, and from a diffusion of culture and literacy came the small self-conscious middle class, which was the most important vehicle for liberal doctrine. Scientific discovery and technological innovation, capitalist methods of economic venture, modified legal concepts, and new forms of property worked reciprocally, especially from the sixteenth through the eighteenth centuries, to provide both the opportunity and the incentives for individual and group initiative. The consequence was the increase not only of a small commercial and industrial middle class but, even more important, the spread of attitudes hospitable to individual enterprise and to the creed of individual responsibility.

A comparatively rapid and wide diffusion of enlightened and cosmopolitan attitudes among social and political elites, as well as among burghers,

professional men, merchants, and country gentry, was of enormous importance to the development of liberalism, especially in the later seventeenth and eighteenth centuries. This development depended upon and grew from the earlier humanism and enlightenment of the Renaissance and Reformation. But the earlier tradition had been restricted largely to the court, the city, and the clergy. During the eighteenth century the arts and the sciences, political life, and a comparatively sophisticated culture became accessible to a much wider circle. Many more read; many more discussed.

Liberalism, viewed in historical perspective, was the culmination of several broad social and political trends. It involved a change in the scope of individual aspirations and, perhaps more important, in the people who had them. Prior to the nineteenth century these aspirations were restricted to an elite of birth and wealth. Social environment, individual aspiration, and consciousness of capacity combined to produce, in the nineteenth century, a widely shared and politically potent liberal faith.

Classical liberalism

Liberalism, both as a doctrine and as a political program, developed most fully in England between the Glorious Revolution (1688) and the Reform Act of 1867. Liberalism was first a limited appeal for constitutional guarantees and individual rights. It became a positive theory of economic and political organization and a political program with broad national appeal extending to many groups and classes. Neither on the Continent nor in the United States did early liberalism develop in a similar fashion. The experience of England stands alone; and the term "classical liberalism" is ordinarily used with reference to England.

Liberalism in England first took the form of a demand for religious liberties and toleration, constitutionalism, and political rights. During the Puritan revolution and the Commonwealth, written constitutions were proposed and pamphlets published demanding a number of liberties. Digger and Leveller tracts, the pamphlets of John Lilburne, the more reflective *Commonwealth of Oceana* of James Harrington, and Milton's exalted defense of free speech in *Areopagitica* not only illustrate the scope of the constitutional controversy but also afford a sample of the political literature of the period. The revolution of 1688, the first "liberal revolution" in history, consolidated and gave definite constitutional form to the liberal gains of that century. The liberalism recognized and vindicated in 1689 was essentially negative in character, pro-

tecting groups and individuals from government, especially from the prerogatives of the crown. It was also aimed at securing chiefly political rather than economic objectives. Among those political objectives are some of the most important principles of liberal constitutionalism: the right of opposition, the rule of law, and the separation of powers. The settlement also included a recognition of important civil liberties by acts securing toleration, in 1688, and liberty of the press, in 1695. Locke's *Second Treatise of Government* and the American Declaration of Independence stand as the great monuments of this phase of liberalism. [See CONSTITUTIONS AND CONSTITUTIONALISM; and the biography of LOCKE.]

The constitutional settlement and civil peace gave enormous impetus to a second theme of classical liberalism: the theory and practice of economic liberty. The English liberal economists, led by Adam Smith, were neither the first nor the only group to erect a theory upon the postulate of laissez-faire, but they were the most influential. Their ideals were: in the juridical sphere, free contract and the rule of law; in the economic sphere, a self-regulating market, unrestrained either by monopoly or political intervention; and in the social sphere, voluntarism and collaboration for mutual benefit. The laissez-faire doctrine and the practical organization of the economy that the classical economists advocated greatly strengthened liberalism. They did so, first of all, because they broadened and democratized the values of liberalism, extending them to mercantile, commercial, and laboring classes. Second, they did so because they encouraged forms of social and economic activity that could substitute for more compulsive and bureaucratic techniques of regulation. Thus, the point of Adam Smith's "obvious and simple system of natural liberty" was not only that it was "free" and "impersonal" but—equally important—that it was a "system" allowing men to exert their energies both to their own and to the common benefit [see LAISSEZ-FAIRE; SMITH, ADAM].

The English utilitarians and their political allies completed the edifice of classical liberalism. Jeremy Bentham and James Mill accepted the market economy and especially the ideals it served. They accepted, for the most part, the aims but not the methods of the liberalism of 1689. They brought the two species of liberalism together by applying the concepts of utility and the market to politics and the tasks of constitutionalism. Arguing from the hedonistic calculus and the principle of equality, they advocated "the greatest good of the greatest number." They insisted in law and politics upon

general rules that provide for a maximum of free choice and practical liberty for all, or as many as consonant with general utilitarian maxims. And they argued that only education and free speech, inclusive representation and an expanded suffrage, and the regular accountability of the governors to the governed—politics organized on the model of the free economy—could provide constitutional security and good government. English utilitarianism, as propounded by Bentham and James Mill, provided a philosophical foundation for political liberalism. It also unified economic liberalism with a theory of positive political action. Properly, this utilitarian doctrine deserves the title of the first comprehensive liberal philosophy [see BENTHAM; MILL; UTILITARIANISM].

Classical liberalism in England owed much of its success to the fact that three liberal traditions—constitutionalism, economic liberalism, and utilitarianism—each developing in a different historic period and having a different group appeal, could be effectively joined in practical politics. Liberalism in England became a party with a broad appeal and sustained its appeal for many years. At the time of the corn law repeal (1846) liberalism in England had its broadest support, including many Whigs, Cobden and Bright liberals, utilitarians, and middle-class and working-class adherents. Probably this alliance marked the natural limits of the older liberalism. It also occupied the common meeting ground of several varieties of liberal program and ideology. Liberalism at this point in England achieved a maximum synthesis of its two competing themes: noninterference and enfranchisement.

Liberalism in Europe and America

Two vital conditions for a classical liberal synthesis existed only in England—a broad liberal movement and a powerful liberal party. In the United States the second condition was missing; on the Continent, the first.

In the United States classical liberalism did not exist, partly because conservatism in the European sense did not exist either. From Europe, Americans inherited the libertarian precepts of the Puritan revolution, the Whig settlement of 1689, and some liberal economic values. These were "received" in the colonial tradition and figured in the American Revolution, the Constitutional Convention, and, broadly, in the politics and jurisprudence of the developing nation. But they were a part of the national heritage and the spirit of the laws, not the self-conscious creed of a party or a class. Liberalism as such did not need to be vindicated, nor did

it have a specific role to play. Moreover, liberalism was mixed with other issues of democracy and equality, as, for instance, in the eras of Jefferson and Jackson. When, in the late nineteenth and early twentieth centuries, social Darwinism and natural-rights jurisprudence were erected into a creed of noninterference and supposed liberty, they were already "ideology" and not "utopia." America was, then, in large measure the unreflective inheritor of classical liberalism, especially the Lockean variety. Conscious or self-conscious liberalism in America came with the second phase of liberal development—the transition to a modern liberalism.

The classical liberal synthesis was sought in Europe but never fully achieved. Instead of developing into a broad and powerful movement and a comparatively effective political party, European liberalism remained fragmented and sectarian. Civil and religious strife and the slow development of commerce and industry contributed to this result. So did war. The state and the traditions of authority were too strong, liberalism too divided and weak, at the time when a liberal synthesis might have been realized. As a consequence, classical liberalism did not fully develop in Europe; instead several leading liberal creeds arose, which were usually doctrinaire in social philosophy and narrowly based in group support.

In Europe the primary task of securing and protecting the rule of law and constitutionally sanctioned liberties was more difficult. That task tended to become, for some European liberals, almost an end in itself, creating a liberal philosophy that Guido de Ruggiero (1925) has called "guarantism." Unfortunately, what needed to be guaranteed in the interests of constitutionalism were often ancient liberties and privileges that because of their oligarchic origins and reactionary tendency worked against a more common liberty and the general good. Consequently, one species of European liberalism was decidedly aristocratic, supporting not only liberty but also the inequitable privileges of localities, corporations, and social and religious groups. Montesquieu and Benjamin Constant afford good illustrations of aristocratic liberalism in political theory. The Restoration and the July Monarchy in France and the revolt of 1848 in Germany are historic tragedies of this divided heritage of European liberalism.

Rationalistic and utilitarian liberalism found expression, during the age of reason and afterward, primarily in an appeal for reform from above. The *philosophes* in France and German liberals such as Goethe and Herder adopted the goals of individu-

alism, widened liberty, and a rational code of laws. They did not associate these objectives with political liberty or popular participation. For some the ideal was enlightened despotism and utilitarian standards, whatever the cost to particular and historic liberties or a constitutional tradition. The reform of civil and administrative institutions for liberal ends took precedence over the liberal method. And the liberal tradition was further divided within itself: some liberals espoused a despotic method, and others such as Rousseau, Fichte, and Mazzini sought the liberal spirit in a "general will" or "the people." Louis Bonaparte in France and Bismarck in Germany built much of their power upon this division.

In Europe there were liberal economic theorists, such as Jean Baptiste Say, Frédéric Bastiat, and Friedrich von Hermann; there were also middle-class political movements and parliamentary factions supporting laissez-faire and free trade. But Europe lacked the well-grown middle class and the economic, legal, and political environment needed to make the cause of economic freedom effective and, more important, to give liberalism a central direction. As a consequence, economic liberalism remained too long the creed of a part of the bourgeoisie and an intellectual preoccupation for scholars and a few publicists. Later, when economic liberalism was both possible and widely adopted—for instance, in the French Third Republic and in unified Italy—that policy served less fully the original liberal objectives of expanding liberty and equalizing opportunity. Economic circumstances made laissez-faire, as socialists protested, not a service to liberty as a whole but to the interests of a comparatively small number of economically advantaged individuals.

At an early stage, in Europe, liberalism failed because it was weak and divided. In the later decades of the nineteenth century it was "too late" for classical liberalism. This is not to say that liberalism was not a vitally needed political and doctrinal element of European society: it was. But liberalism had to appeal to a radically changed world, one in which democracy or republicanism, nationalism, and socialism were the popular gospels.

Modern liberalism

In the late nineteenth and early twentieth centuries classical liberalism and the traditions of thought and policy closely related to it were progressively modified. Later liberalism—especially in Great Britain and the United States, but to some extent almost everywhere in the modern world—has emphasized the positive rather than the nega-

tive aspect of liberty: the opportunity to form and accomplish self-appointed goals, rather than freedom from the state. Along with this shifting of proximate goals of liberalism came an adoption of new methods. The central value of the liberated individual, of man as far as possible his own sovereign, did not change; the understanding of that value and of the means for achieving it did.

An important cause of this revision was the success of liberalism itself: the securing of a considerable measure of political and economic liberty and the conversion of liberalism from a sectarian demand for noninterference into a program of political and economic organization. Success raised not only the question, What next? but also, Liberty for whom? Aristocrats and the bourgeoisie now had substantially the bundle of rights they needed. The franchise gave them the means of self-defense. But the same concessions—even when granted—were not enough for the peasant or the worker. Effective liberty for them required more positive action by the state, a fact that conservatives, Catholic social theorists, and Marxian and other socialists pointed out emphatically.

Liberal reorientation came partly through challenge and response, from a need to meet political and philosophical criticism. Liberalism was itself a philosophical and reasonable doctrine and therefore responsive to the new theories of man and society announced by nineteenth-century scientists and made popular by parliamentary inquiry, governmental commissions, and the newspapers. Politics was also important. The varied appeals of Tory Democracy in England, Louis Bonaparte's imperialism in France, and monarchical socialism in Germany were political forces that could not be ignored. Nor could a liberalism that served principally the bourgeoisie of the French Second Republic or the textile manufacturers of Manchester prosper in an age of the expanded franchise, effective mass communications, and social consciousness. The liberalism that survived after 1848 had, perforce, to accommodate itself to democratic, nationalist, and socialist sentiment.

The growth of cities, of industry, and of national and world-wide commerce also forced revisions of the liberal position. Earlier liberal theory, with its individualistic premises, had contrived a model of man, his institutions, and society that minimized the facts of organizational power, of community cost and benefit, and of national history and common fate. Time progressively falsified that model, especially after the growth of the modern corporation and industrial technology. Great inequalities in market power made one man's eco-

nomic freedom another's oppression. Similarly, free trade in commodities—such as child labor, slum housing, poisoned meat, and bad gin—made the common benefit of regulation obvious. Liberals split among themselves. One group argued for a remedy of abuses other than those perpetrated by the state. Another group clung to the dogmas of nonintervention and free trade. They made the means of liberalism into ends in themselves and liberalism itself into a conservative ideology. Thus, one heir of Bentham and Adam Smith is John Stuart Mill, and another is Herbert Spencer [see SPENCER].

With consciousness of changed circumstances came a major reassessment of the means to liberty. Later liberals assigned greater importance to the social environment within which liberty had to be realized. Their revision of liberalism followed from a recognition that certain forms of coercion and obstacles to liberty arise from society itself rather than the activities of officials. The revision had another important foundation. A society of great economic and social interrelatedness makes access to culture, the capacity to participate, and membership and status in natural and artificial groups increasingly important both to the pursuit of liberty and to its defense. Rousseau and Hegel, and, later, T. H. Green and John Dewey, all argued this theme. Man is in society, the point at which many impinging groups, institutions, and cultural influences intersect. Seldom can he effectively withdraw. He can realize and defend his liberty only by participation. But a live option of participation does not simply happen: it is a social product depending upon education, incentive, opportunity, and a supporting system of political and social values. Modern liberalism tends necessarily, therefore, to be closely associated not only with social reform but with democracy and popular participation.

The modern liberal's view of the individual is also different from the classical description. It was not merely that the life and goals that suited a Bentham or an English merchant would distress a Coleridge, a Cardinal Newman, and, indeed, even a John Stuart Mill. The earlier liberal view of human nature was two dimensional and overly rationalistic. Nineteenth-century sociology and psychology destroyed that view thoroughly. Modern liberalism has assimilated much of the critique. Liberals today see man not only as an individual in society but as a person with a continuing need for self-expansion and reintegration. For this reason the emphasis of modern liberalism is less upon external impediments to motion and more upon the individual person's subjective feeling of freedom and

those circumstances that give to this feeling an objective reality in the experience of the individual. If a man does not feel free, he is not free. [See PERSONALITY, POLITICAL.]

One question that arises is whether modern, or "revised," liberalism can still appropriately be called liberalism. Liberty and equality, rights and powers are not the same things. Modern liberalism advocates collectivist means, invoking the state in aid of individuals and disadvantaged groups. It has adopted much of the program of democratic and socialist movements. Is modern liberalism still "liberal"? Three considerations argue that this query be answered with a qualified affirmative. In the first place, modern liberalism retains the same end of the autonomous individual that has guided all true liberalism. The means to that end and proximate ends have changed, but the final end remains the same. Second, those changes in method and policy that most writers identify with the expansion and modernization of liberalism have served not only to reduce arbitrary compulsion but also to extend the scope, equalize the distribution, and enrich the liberty enjoyed by individuals. Third, constitutional rights and the rule of law not only survive in the mixed regime of liberty, democracy, and the administrative state but have in some ways grown stronger. They are stronger to the extent that the mixed regime is a representative one—in which the state cannot be used as a tool for the purposes of any *one* group or class but must serve and be responsive and accountable to *all*. Certainly, modern liberalism invokes the coercive power of the state. In relation to the state itself men are, in some ways, less free to do with their own as they please. For this reason it is important that the options open to men be many and that the relations of state, society, and individual afford alternate ways of suiting means to essential ends. Pluralism, decentralization, and a variety of relations between the state and society answer to these needs. They probably afford men, given an established welfare state, a better marginal choice in distributing their energies and opting for one of several modes of liberty than ever before in history. [See WELFARE STATE.]

The future of liberalism

Although liberalism has been important to Western civilization, it may not continue to be so. Since the two world wars, many argue, liberalism has been in decline. Liberalism means less, so the argument runs, to the developing nations, to the semi-socialist states of western Europe, to a world menaced with war and preoccupied with material

benefit. Liberal parties and liberal ideology, it could also be argued, have served their function. The programs they supported have been adopted by others who have gone further. Historic liberalism survives only as a temper or mood of politics.

Liberal parties and liberal movements have been on the wane. In the British Commonwealth and Europe they have not fared well since World War II. Some maintain their electoral following, but mainly by altering their liberal stance. Specific movements, such as the neoliberalism of Germany and the Low Countries or the Mouvement Republicain Populaire of France, show an attrition of membership, unity, and purpose. The conclusion that liberalism as an organized party or self-conscious movement is for the present in decline is warranted by the facts. In no place, presently, are liberal parties or liberal movements gaining significantly in organized power or appeal.

Liberal policies have also received scant support among developing nations struggling for independence and material prosperity. The conditions that made Adam Smith's strategy of liberty suitable for England are missing today. Even such countries as Mexico and India, which seem determined to save liberty, are far from classical liberalism and even from more modern versions of liberalism. They are nationalistic and socialistic in many of their policies and are so by conscious intent and design.

The cold war has also weakened liberalism. In the short run, the communist challenge threatens liberty and constitutionalism directly. In the longer run, the danger is more insidious: external threats evoke response; and response demands collective effort. That effort is stimulated by nonliberal incentives and appeals: appeals to national purpose and common action and the incentives of a war economy. Liberty is not broken; but it shrinks. Liberalism is not vanquished; but it is not pursued. If, as John Stuart Mill said, "things left to themselves inevitably decay," the threat is greater than at first sight it appears. The danger to liberalism is not that it will be openly destroyed but that it will be forgotten or perverted.

From these facts it does not follow that liberalism is unimportant for the future. The importance of the liberal temper and of liberal principles applied to politics has not diminished; probably it has increased. Liberalism thrives on material prosperity, social peace, and common enlightenment. In the programs of the nations of western Europe immediately after World War II liberalism did not have a prominent place, nor has it been important in the programs of the developing nations. These nations have been engaged in creating the condi-

tions of material prosperity and economic security. Hopefully, their labor will eventually bear fruit in comparatively stable, pluralistic democracies and welfare economies capable of providing security and abundance for their populations. Such developments would not make liberalism outmoded. They would, in fact, make it possible and profitable: for they make it possible to realize liberty along with abundance and social justice; and they make the finer qualities of human relations increasingly accessible and valuable to all.

LICENSING, OCCUPATIONAL

In labor markets in which the rule of free choice prevails, individuals may enter and leave occupations without securing the consent of private or public authorities. Occupational licensing limits the range within which free choice governs. Occupational licensing occurs where a profession, trade, or occupation may be legally practiced only by those who have been authorized to do so by some agency of government.

Occupational licensing should be distinguished from certification. In the former case, the law permits only licensed persons to practice; in the latter, anyone may practice but only certified persons may use the relevant occupational title in notifying the public that their services are available. It is also different from the licensing of businesses, although that sometimes involves occupational licensing implicitly.

Occupational licensing is extensive in the United States, where the licensing authorities are usually agents of the states or of municipalities, rather than of the federal government. The practice of a few occupations does require a federal license. Gellhorn (1956, p. 106) found that state licenses were required in one or more states for the practice of some eighty occupations. State legislatures and municipal legislative organs routinely receive proposals that additional occupations be licensed. In countries other than the United States, licensing is apparently less common but it does occur.

Justification. When legislatures enact occupational licensing legislation, they usually do so on grounds that the public health, safety, or morals are being protected. In the absence of provision for licensing, it is reasoned, incompetent practitioners will offer their services. Prospective buyers of these services are said not to be able to distinguish between qualified and unqualified persons, and this is considered to be especially true if consumers buy services of the particular kind only at infrequent intervals. Where the consequences of the employment of unqualified persons can be expected

to be seriously adverse to the purchaser, and especially where the consequences of incompetently rendered service are irreversible, it is thought to be desirable that the state administer some examining or other procedure to determine who are qualified to practice, and prevent those who are unqualified from offering their services. The average quality of those permitted to practice is raised, and by the exclusion of "quacks" and incompetents the public is protected from the error of employing them.

Thus, occupations that are licensed are concentrated in the tertiary sector of the economy, in which self-employment is common and services are purchased by any given buyer only infrequently. Information about professional competency that is produced by employment over a long period is not easily available in such cases to would-be purchasers. (A sophisticated exposition of the reasons for licensing in the special case of medical care can be found in Arrow 1963.)

While there are some licensed occupations for which the foregoing line of reasoning is sensible, there are others for which it seems far-fetched.

Certification, although it permits anyone to practice, nevertheless diminishes uncertainty, as does licensing, by informing prospective buyers which of those in the occupation have successfully passed the state examination and which have not. Neither licensing nor certification reduces uncertainty to zero, because there is variance in the competency of those who are licensed or certified and consumers must still search out additional information.

The requests that come to legislatures that an occupation be licensed or that the qualifying standards of an already-licensed occupation be raised rarely come from coalitions of consumers but almost always from associations of practitioners of the occupation. These requests are almost always accompanied by the proposal that those who have already entered and are practicing the occupation be qualified *pro forma* and exempted from examination. Such a "grandfather clause" often appears in occupational licensing legislation; only those desiring to enter the occupation are subjected to the qualifying tests. It is also common for states and municipalities to appoint already-licensed practitioners to examining boards that determine whether applicants for entry into licensed trades and professions are qualified. In addition, professional and trade associations of those in licensed occupations are the most watchful and aggressive in preventing others from performing services the associations believe to be exclusively comprehended by their particular occupation.

The circumstances just described could reflect the desire of practitioners to assure consumers that they will secure only competent services. However, it is more likely that they reflect the hopes of practitioners for higher incomes, for licensing frequently causes the price of service and the earnings of practitioners in licensed occupations to be higher than they would be if the occupations were unlicensed.

Economic effects. Whether economic effects occur depends upon the nature of the qualifying rules. If these do not check entry into the occupation, prices and earnings will be left unaffected. If entry is checked, they will be higher than they would have been had there been no licensing. The magnitude of the difference is determined by the degree to which the qualifying rules of licensure check entry and by the extent of change in the quantities of the relevant services that sellers are willing to sell and buyers are willing to buy as their prices change—that is to say, by the price elasticities of supply and demand. An estimate of the relative income effects of licensure in medicine and dentistry in the United States for the period 1929 to 1934 was made by Friedman and Kuznets (1945, chapter 4). The Friedman and Kuznets estimate is discussed by Lewis (1963, p. 114 ff.), who also makes a similar estimate for a more recent period.

Not all occupational licensing causes prices and earnings to rise, because in some licensed occupations almost all qualify and entry is not checked. This is the case if licenses are granted to all who are "of good moral character." Licensing arrangements of this kind are usually adopted in order to facilitate the administration of some standard of conduct by practitioners. Illustratively, a rule that in massage parlors men clients are to be separated from women clients can be conveniently enforced by the revocation of the licenses of masseurs who violate the rule. Most occupational licensing, however, does check entry, by imposing either explicit or implicit costs of entry in addition to those which would be incurred in the absence of licensing.

Explicit additional entry costs may include required general schooling, of some specified level; vocational or professional schooling, for some period or containing a specified content; successful performance upon written or oral examination; and employment for some period as an apprentice, with relatively low earnings. The explicit costs are the sum of tuition charges and other fees paid for schooling, and the income forgone that might have been earned if other employment had been taken during the required period of schooling and apprenticeship.

Implicit entry costs are, for example, a minimum-age qualification or a limitation on the number of licenses that will be issued. For those who do not qualify under such rules, the implicit cost of entry into the occupation is infinite.

Not infrequently, persons seeking to be licensed in some occupation are examined in subject matter that has no immediate relevance to the skills that will be ordinarily performed in it. In this way specialization in the acquisition of skill is discouraged. This is done, apparently, in order to prolong the period of training in preparation for the examination, thus increasing the cost of new entry into the occupation.

If the cost of entry is raised—either because incremental costs are imposed by licensure or for any other cause—fewer people will make themselves available to that occupation at every hypothetical level of relative earnings in it. In the conventional graphic representation of market schedules, a rise in entry costs shifts the supply schedule of labor in that occupation to the left. The point of intersection of the supply and demand schedules, which determines the price paid to labor in the occupation and (to a first approximation) the number who are employed in it, is now such that earnings in the trade will be higher and the number who are employed in it will be less than if there had been no increase in the cost of entry.

This is not to say that there are necessarily monopoly gains for those who are employed in the occupation. In principle, the rise in earnings will be just sufficient to compensate for the rise in entry costs. Those who have incurred the increased costs of entry will receive earnings that, when adjusted for the higher cost of entry, will just equal the earnings of those who are in similar occupations which are freely entered and for which licensure has not created an additional increment to the cost of entry.

But there will be monopoly gains—rents—for those in a licensed occupation who have *not* been required to incur the extra entry costs imposed by licensure or by higher qualifying standards. It is therefore understandable that practitioners in unlicensed occupations frequently propose that their occupations be licensed—with grandfather clauses that will qualify them *pro forma*—and that practitioners in licensed occupations propose higher qualifying standards for entry than those they were required to satisfy when they entered. Any increase in entry costs will check entry into the occupation and cause earnings to rise. This will produce rents for those already in the occupation, who are exempted from incurring the additional cost.

Rationing problem. If the licensing rules impose entry costs, a smaller number will be employed in the occupation than if there had been no licensing. But if licensing rules permit *all* who meet the qualifying standards to enter an occupation, there will be no explicit rationing problem. The number employed will be determined by the point of intersection of demand and supply schedules; the number making themselves available in the occupation will be just equal to the number whose services buyers want to buy, and the market will clear.

This may not be true, however, when explicit limits are put upon the number of licenses to be issued by the public authorities. This arrangement occurs in a minority of cases. In these cases, rationing may be necessary when, given the cost of entry and relative earnings in the licensed occupation, more qualify and seek to enter it than there are licenses available. Here the relevant agency of government must act on some principle that distinguishes those who will be granted a license from those who will be rejected. The rule may be of a first-come-first-served type—as when available licenses are issued to those who have waited longest for one—or it may be of some other nature. If the authorities, having predetermined the number of licenses they will issue, sell them by some auction procedure to the highest bidders, market processes will, of course, determine the distribution of licenses among prospective entrants to the occupation and the market will clear.

In some cases the authorities, after numerically limiting licenses to be issued for some occupation and rationing them among applicants for a nominal charge, have permitted these licenses to be privately transacted. Here the licenses, which give access to employment in the occupation exclusively to those who hold them, are capital assets whose values depend upon the time-discounted stream of monopoly rents (net earnings, over time, that exceed those that would be attached to the occupation if there were free access to it). The capital value of these licenses—that is to say, the prices at which they are transacted—may rise or fall in successive transactions. If their prices do change, it is because the future has not been perfectly foreseen by sellers or buyers in prior transactions with respect to any one or a number of relevant variables that affect the monopoly gains associated with the possession of a license.

Licensing checks on entry into an occupation only rarely use the strategy of explicit numerical limitation of licenses to be issued; the alternative device

of imposing new entry costs is much more commonly employed. The latter device can be associated with the raising of standards of performance and qualification in the trade. The enforcement of numerical limits, on the other hand, can be defended only on the ground that unlimited entry will have adverse effects on third parties, for example, that unlimited numbers of taxis, competitively racing for customers, will cause accidents. Legislatures seem to find the defense-of-standards argument more attractive. If requirements for acquisition of the license exclude those who fall below some prescribed minimum of capacity or knowledge relevant to the service rendered in an occupation, the mean standard of performance by legal practitioners of a licensed occupation will, of course, be higher than if the occupation were unlicensed. In such a case, the mean quality of this service that is purchased by consumers will usually also be higher. But this result does not always occur. Whether it does depends on the substitute to which consumers have recourse when the law denies them access to low-priced, low-quality professional services.

The number of persons in licensed occupations is still a small proportion of all employed persons in the United States, but their relative numbers seem to be increasing as more and more legislatures respond to the overtures of practitioners and more and more occupations are licensed.

LIFE CYCLE

The observer of life is always immersed in it and thus unable to transcend the limited perspectives of his stage and condition. Religious world views usually evolve pervasive configurations of the course of life: one religion may envisage it as a continuous spiral of rebirths, another as a crossroads to damnation or salvation. Various "ways of life" harbor more or less explicit images of life's course: a leisurely one may see it as ascending and descending steps with a comfortable platform of maturity in between; a competitive one may envision it as a race for spectacular success—and sudden oblivion. The scientist, on the other hand, looks at the organism as it moves from birth to death and, in the larger sense, at the individual in a genetic chain; or he looks at the cultural design of life's course as marked by rites of transition at selected turning points.

The very choice of the configuration "cycle of life," then, necessitates a statement of the writer's conceptual ancestry—clinical psychoanalysis. The clinical worker cannot escape combining knowledge, experience, and conviction in a conception of the course of life and of the sequence of generations—for how, otherwise, could he offer interpretation and guidance? The very existence of a variety of psychiatric "schools" is probably due to the fact that clinical practice and theory are called upon to provide a total orientation beyond possible verification.

Freud confessed only to a scientific world view, but he could not avoid the attitudes (often in contradiction to his personal values) that were part of his times. The original data of psychoanalysis, for example, were minute reconstructions of "pathogenic" events in early childhood. They supported an orientation which—in analogy to teleology—could be called *originology*, i.e., a systematic attempt to derive complex meanings from vague beginnings and obscure causes. The result was often an implicit fatalism, although counteracted by strenuously "positive" orientations. Any theory embracing both life history and case history, however, must find a balance between the "backward" view of the genetic reconstruction and the "forward" formulation of progressive differentiation in growth and development; between the "downward" view into the depth of the unconscious and the "upward" awareness of compelling social experience; and between the "inward" exploration of inner reality and the "outward" attention to historical actuality.

This article will attempt to make explicit those psychosocial insights that often remain implicit in

clinical practice and theory. These concern the individual, who in principle develops according to predetermined steps of readiness that enable him to participate in ever more differentiated ways along a widening social radius, and the social organization, which in principle tends to invite such developmental potentialities and to support the proper rate and the proper sequence of their unfolding.

"Cycle" is intended to convey the double tendency of individual life to "round itself out" as a coherent experience and at the same time to form a link in the chain of generations from which it receives and to which it contributes both strength and weakness.

Strategic in this interplay are developmental crises—"crisis" here connoting not a threat of catastrophe but a turning point, a crucial period of increased vulnerability and heightened potential, and, therefore, the ontogenetic source of generational strength and maladjustment.

The eight stages of life

Man's protracted childhood must be provided with the psychosocial protection and stimulation which, like a second womb, permits the child to develop in distinct steps as he unifies his separate capacities. In each stage, we assume a new drive-and-need constellation, an expanded radius of potential social interaction, and social institutions created to receive the growing individual within traditional patterns. To provide an evolutionary rationale for this (for prolonged childhood and social institutions must have evolved together), two basic differences between animal and man must be considered.

We are, in Ernst Mayr's terms (1964), the "generalist" animal, prepared to adapt to and to develop cultures in the most varied environments. A long childhood must prepare the newborn of the species to become specialized as a member of a pseudo species (Erikson 1965), i.e., in tribes, cultures, castes, etc., each of which behaves as if it were the only genuine realization of man as the heavens planned and created him. Furthermore, man's drives are characterized by instinctual energies, which are, in contrast to other animals, much less bound to instinctive patterns (or inborn release mechanisms). A maximum of free instinctual energy thus remains ready to be invested in basic psychosocial encounters which tend to fix developing energies into cultural patterns of mutuality, reliability, and competence. Freud has shown the extent to which maladaptive anxiety and rage accompany man's instinctuality, while postulating

corporate by mouth and through the senses meets the mother's and the society's more or less coordinated readiness to feed him and to stimulate his awareness. The mother must represent to the child an almost somatic conviction that she (his first "world") is trustworthy enough to satisfy and to regulate his needs. But the infant's demeanor also inspires hope in adults and makes them wish to give hope; it awakens in them a strength which they, in turn, are ready and needful to have confirmed in the experience of care. This is the ontogenetic basis of hope, that first and basic strength which gives man a semblance of instinctive certainty in his social ecology.

Unavoidable pain and delay of satisfaction, however, and inexorable weaning make this stage also prototypical for a sense of abandonment and helplessness. This is the first of the human estrangements against which hope must maintain itself throughout life.

In psychopathology, a defect in basic trust can be evident in early malignant disturbances or can become apparent later in severe addiction or in habitual or sudden withdrawal into psychotic states.

Biological motherhood needs at least three links with social experience—the mother's past experience of being mothered, a method of care in trustworthy surroundings, and some convincing image of providence. The infant's hope, in turn, is one cornerstone of the adult's faith, which throughout history has sought an institutional safeguard in organized religion. However, where religious institutions fail to give ritual actuality to their formulas they may become irrelevant to psychosocial strength.

Hope, then, is the first psychosocial strength. It is the enduring belief in the attainability of primal wishes in spite of the anarchic urges and rages of dependency.

Early childhood (autonomy versus shame, doubt—will power). Early childhood sets the stage for psychosocial autonomy by rapid gains in muscular maturation, locomotion, verbalization, and discrimination. All of these, however, create limits in the form of spatial restrictions and of categorical divisions between "yes and no," "good and bad," "right and wrong," and "yours and mine." Muscular maturation sets the stage for an ambivalent set of social modalities—holding on and letting go. To hold on can become a destructive retaining or restraining, or a pattern of care—to have and to hold. To let go, too, can turn into an inimical letting loose, or a relaxed "letting pass" and "letting be." Freud calls this the anal stage of libido development because of the pleasure experienced in and the conflict evoked over excretory retention and elimination.

This stage, therefore, becomes decisive for the ratio of good will and willfulness. A sense of self-control without loss of self-esteem is the ontogenetic source of confidence in free will; a sense of overcontrol and loss of self-control can give rise to a lasting propensity for doubt and shame. The matter is complicated by the different needs and capacities of siblings of different ages—and by their rivalry.

Shame is the estrangement of being exposed and conscious of being looked at disapprovingly, of wishing to "bury one's face" or "sink into the ground." This potentiality is exploited in the "shaming" used throughout life by some cultures and causing, on occasion, suicide. While shame is related to the consciousness of being upright and exposed, doubt has much to do with the consciousness of having a front and a back (and of the vulnerability of being seen and influenced from behind). It is the estrangement of being unsure of one's will and of those who would dominate it.

From this stage emerges the propensity for compulsive overcompliance or impulsive defiance. If denied a gradual increase in autonomy of choice the individual may become obsessed by repetitiveness and develop an overly cruel conscience. Early self-doubt and doubt of others may later find their most malignant expression in compulsion neuroses or in paranoid apprehension of hidden critics and secret persecutors threatening from behind.

We have related basic trust to the institutions of religion. The enduring need of the individual to have an area of free choice reaffirmed and delineated by formulated privileges and limitations, obligations and rights, has an institutional safeguard in the principles of law and order and of justice. Where this is impaired, however, the law itself is in danger of becoming arbitrary or formalistic, i.e., "impulsive" or "compulsive" itself.

Will power is the unbroken determination to exercise free choice as well as self-restraint in spite of the unavoidable experience of shame, doubt, and a certain rage over being controlled by others. Good will is rooted in the judiciousness of parents guided by their respect for the spirit of the law.

Play age (initiative versus guilt—purpose). Able to move independently and vigorously, the child, now in his third or fourth year, begins to comprehend his expected role in the adult world and to play out roles worth imitating. He develops a sense of initiative. He associates with age-mates and older children as he watches and enters into games in the barnyard, on the street corner, or in the nursery. His learning now is intrusive; it leads him into ever new facts and activities, and he becomes acutely aware of differences between the sexes. But

if it seems that the child spends on his play a purposefulness out of proportion to "real" purposes, we must recognize the human necessity to simultaneously bind together infantile wish and limited skill, symbol and fact, inner and outer world, a selectively remembered past and a vaguely anticipated future—all before adult "reality" takes over in sanctioned roles and adjusted purposes.

The fate of infantile genitality remains determined by the sex roles cultivated and integrated in the family. In the boy, the sexual orientation is dominated by phallic-intrusive initiative; in the girl, by inclusive modes of attractiveness and "motherliness."

Conscience, however, forever divides the child within himself by establishing an inner voice of self-observation, self-guidance, and self-punishment. The estrangement of this stage, therefore, is a sense of guilt over goals contemplated and acts done, initiated, or merely fantasied. For initiative includes competition with those of superior equipment. In a final contest for a favored position with the mother, "oedipal" feelings are aroused in the boy, and there appears to be an intensified fear of finding the genitals harmed as punishment for the fantasies attached to their excitability.

Infantile guilt leads to the conflict between unbounded initiative and repression or inhibition. In adult pathology this residual conflict is expressed in hysterical denial, general inhibition, and sexual impotence, or in overcompensatory exhibitionism and psychopathic acting-out.

The word "initiative" has for many a specifically American, or "entrepreneur," connotation. Yet man needs this sense of initiative for whatever he learns and does, from fruit gathering to commercial enterprise—or the study of books.

The play age relies on the existence of some form of basic family, which also teaches the child by patient example where play ends and irreversible purpose begins. Only thus are guilt feelings integrated in a strong (not severe) conscience; only thus is language verified as a shared actuality. The "oedipal" stage thus not only results in a moral sense restricting the horizon of the permissible, but it also directs the way to the possible and the tangible, which attract infantile dreams to the goals of technology and culture. Social institutions, in turn, offer an ethos of action, in the form of ideal adults fascinating enough to replace the heroes of the picture book and fairy tale.

That the adult begins as a playing child means that there is a residue of play acting and role playing even in what he considers his highest purposes. These he projects on a larger and more perfect historical future; these he dramatizes in the cere-

monial present with uniformed players in ritual arrangements; thus men sanction aggressive initiative, even as they assuage guilt by submission to a higher authority.

Purpose, then, is the courage to envisage and pursue valued and tangible goals guided by conscience but not paralyzed by guilt and by the fear of punishment.

School age (industry versus inferiority—competence). Before the child, psychologically a rudimentary parent, can become a biological parent, he must begin to be a worker and potential provider. Genital maturation is postponed (the period of latency). The child develops a sense of industriousness, i.e., he begins to comprehend the tool world of his culture, and he can become an eager and absorbed member of that productive situation called "school," which gradually supersedes the whims of play. In all cultures, at this stage, children receive systematic instruction of some kind and learn eagerly from older children.

The danger of this stage lies in the development of a sense of inadequacy. If the child despairs of his skill or his status among his tool partners, he may be discouraged from further learning. He may regress to the hopeless rivalry of the oedipal situation. It is at this point that the larger society becomes significant to the child by admitting him to roles preparatory to the actuality of technology and economy. Where he finds, however, that the color of his skin or the background of his parents rather than his wish and his will to learn will decide his worth as an apprentice, the human propensity for feeling unworthy (inferior) may be fatefully aggravated as a determinant of character development.

But there is another danger: If the overly conforming child accepts work as the only criterion of worthwhileness, sacrificing too readily his imagination and playfulness, he may become ready to submit to what Marx called a "craft-idiocy," i.e., become a slave of his technology and of its established role typology.

This is socially a most decisive stage, preparing the child for a hierarchy of learning experiences which he will undergo with the help of cooperative peers and instructive adults. Since industriousness involves doing things beside and with others, a first sense of the division of labor and of differential opportunity—that is, a sense of the technological ethos of a culture—develops at this time. Therefore, the configurations of cultural thought and the manipulations basic to the prevailing technology must reach meaningfully into school life.

Competence, then, is the free exercise (unimpaired by an infantile sense of inferiority) of dex-

terity and intelligence in the completion of serious tasks. It is the basis for cooperative participation in some segment of the culture.

Adolescence (identity versus identity confusion—fidelity). With a good initial relationship to skills and tools, and with the advent of puberty, childhood proper comes to an end. The rapidly growing youths, faced with the inner revolution of puberty and with as yet intangible adult tasks, are now primarily concerned with their psychosocial identity and with fitting their rudimentary gifts and skills to the occupational prototypes of the culture.

The integration of an identity is more than the sum of childhood identifications. It is the accrued confidence that the inner sameness and continuity gathered over the past years of development are matched by the sameness and continuity in one's meaning for others, as evidenced in the tangible promise of careers and life styles.

The adolescent's regressive and yet powerful impulsiveness alternating with compulsive restraint is well known. In all of this, however, an ideological seeking after an inner coherence and a durable set of values can be detected. The particular strength sought is fidelity—that is, the opportunity to fulfill personal potentialities (including erotic vitality or its sublimation) in a context which permits the young person to be true to himself and true to significant others. "Falling in love" also can be an attempt to arrive at a self-definition by seeing oneself reflected anew in an idealized as well as eroticized other.

From this stage on, acute maladjustments due to social anomie may lead to psychopathological regressions. Where role confusion joins a hopelessness of long standing, borderline psychotic episodes are not uncommon.

Adolescents, on the other hand, help one another temporarily through much regressive insecurity by forming cliques and by stereotyping themselves, their ideals, and their "enemies." In this they can be clannish and cruel in their exclusion of all those who are "different." Where they turn this repudiation totally against the society, delinquency may be a temporary or lasting result.

As social systems enter into the fiber of each succeeding generation, they also absorb into their lifeblood the rejuvenative power of youth. Adolescence is thus a vital regenerator in the process of social evolution, for youth can offer its loyalties and energies to the conservation of that which it feels is valid as well as to the revolutionary correction of that which has lost its regenerative significance.

Adolescence is least "stormy" among those youths

who are gifted and well trained in the pursuit of productive technological trends. In times of unrest, the adolescent mind becomes an ideological mind in search of an inspiring unification of ideas. Youth needs to be affirmed by peers and confirmed by teachings, creeds, and ideologies which express the promise that the best people will come to rule and that rule will develop the best in people. A society's ideological weakness, in turn, expresses itself in weak utopianism and in widespread identity confusion.

Fidelity, then, is the ability to sustain loyalties freely pledged in spite of the inevitable contradictions of value systems. It is the cornerstone of identity and receives inspiration from confirming ideologies and "ways of life."

Young adulthood (intimacy versus isolation—love). Consolidated identity permits the self-abandonment demanded by intimate affiliations, by passionate sexual unions, or by inspiring encounters. The young adult is ready for intimacy and solidarity—that is, he can commit himself to affiliations and partnerships even though they may call for significant sacrifices and compromises. Ethical strength emerges as a further differentiation of ideological conviction (adolescence) and a sense of moral obligation (childhood).

True genital maturity is first reached at this stage; much of the individual's previous sex life is of the identity-confirming kind. Freud, when asked for the criteria of a mature person, is reported to have answered: "*Lieben und Arbeiten*" ("love and work"). All three words deserve equal emphasis.

It is only at this stage that the biological differences between the sexes result in a full polarization within a joint life style. Previously established strengths have helped the two sexes to converge in capacities and values which enhance communication and cooperation, while divergence is now of the essence in love life and in procreation. Thus the sexes first become similar in consciousness, language, and ethics in order then to be maturely different. But this, by necessity, causes ambivalences.

The danger of this stage is possible psychosocial isolation—that is, the avoidance of contacts which commit to intimacy. In psychopathology isolation can lead to severe character problems of the kind which interfere with "love and work," and this often on the basis of infantile fixations and lasting immaturities.

Man, in addition to erotic attraction, has developed a selectivity of mutual love that serves the need for a new and shared identity in the procession of generations. Love is the guardian of that

elusive and yet all-pervasive power of cultural and personal style which binds into a "way of life" the affiliations of competition and cooperation, procreation and production. The problem is one of transferring the experience of being cared for in a parental setting to an adult affiliation actively chosen and cultivated as a mutual concern within a new generation.

The counterpart of such intimacy, and the danger, is man's readiness to fortify his territory of intimacy and solidarity by exaggerating small differences and prejudging or excluding foreign influences and people. Insularity thus aggravated can lead to that irrational fear which is easily exploited by demagogic leaders seeking aggrandizement in war and in political conflict.

Love, then, is a mutuality of devotion greater than the antagonisms inherent in divided function.

Maturity (generativity versus stagnation—care). Evolution has made man the teaching and instituting as well as the learning animal. For dependency and maturity are reciprocal: mature man needs to be needed, and maturity is guided by the nature of that which must be cared for.

Generativity, then, is primarily the concern with establishing and guiding the next generation. In addition to procreativity, it includes productivity and creativity; thus it is psychosocial in nature. From the crisis of generativity emerges the strength of care.

Where such enrichment fails, a sense of stagnation and boredom ensues, the pathological symptoms of which depend on variations in mental epidemiology; certainly where the hypocrisy of the frigid mother was once regarded as a most significant malignant influence, today, when sexual "adjustment" is in order, an obsessive pseudo intimacy and adult self-indulgence are nonetheless damaging to the generational process. The very nature of generativity suggests that the most circumscribed symptoms of its weakness are to be found in the next generation in the form of those aggravated estrangements which we have listed for childhood and youth.

Generativity is itself a driving power in human organization. For the intermeshing stages of childhood and adulthood are in themselves a system of generation and regeneration given continuity by institutions such as extended households and divided labor.

Thus, in combination, the basic strengths enumerated here and the structure of an organized human community provide a set of proven methods and a fund of traditional reassurance with which each generation meets the needs of the next.

Various traditions transcend divisive personal differences and confusing conditions. But they also contribute to a danger to the species as a whole, namely, the defensive territoriality of the pseudo species, which on seemingly ethical grounds must discredit and destroy threateningly alien systems and may itself be destroyed in the process.

Care is the broadening concern for what has been generated by love, necessity, or accident—a concern which must consistently overcome the ambivalence adhering to irreversible obligation and the narrowness of self-concern.

Old age (integrity versus despair—wisdom). Strength in the aging and sometimes in the old takes the form of wisdom in its many connotations—ripened "wits," accumulated knowledge, inclusive understanding, and mature judgment. Wisdom maintains and conveys the integrity of experience, in spite of the decline of bodily and mental functions. Responding to the oncoming generation's need for an integrated heritage, the wisdom of old age remains aware of the relativity of all knowledge acquired in one lifetime in one historical period. Integrity, therefore, implies an emotional integration faithful to the image bearers of the past and ready to take (and eventually to renounce) leadership in the present.

The lack or loss of this accrued integration is signified by a hidden fear of death: fate is not accepted as the frame of life, death not as its finite boundary. Despair indicates that time is too short for alternate roads to integrity: this is why the old try to "doctor" their memories. Bitterness and disgust mask such despair, which in severe psychopathology aggravates senile depression, hypochondria, and paranoid hate.

A meaningful old age (preceding terminal invalidism) provides that integrated heritage which gives indispensable perspective to those growing up, "adolescing," and aging. But the end of the cycle also evokes "ultimate concerns," the paradoxes of which we must leave to philosophical and religious interpreters. Whatever chance man has to transcend the limitations of his self seems to depend on his full (if often tragic) engagement in the one and only life cycle permitted him in the sequence of generations. Great philosophical and religious systems dealing with ultimate individuation seem to have remained (even in their monastic establishments) responsibly related to the cultures and civilizations of their times. Seeking transcendence by renunciation, they remain ethically concerned with the maintenance of the world. By the same token, a civilization can be measured by the meaning which it gives to the full cycle of life, for such

meaning (or the lack of it) cannot fail to reach into the beginnings of the next generation and thus enhance the potentiality that others may meet ultimate questions with some clarity and strength.

Wisdom, then, is a detached and yet active concern with life in the face of death.

Conclusion

From the cycle of life such dispositions as faith, will power, purposefulness, efficiency, devotion, affection, responsibility, and sagacity (all of which are also criteria of ego strength) flow into the life of institutions. Without them, institutions wilt; but without the spirit of institutions pervading the patterns of care and love, instruction and training, no enduring strength could emerge from the sequence of generations.

We have attempted, in a psychosocial frame, to account for the ontogenesis not of lofty ideals but of an inescapable and intrinsic order of strivings, which, by weakening or strengthening man, dictates the minimum goals of informed and responsible participation.

Psychosocial strength, we conclude, depends on a total process which regulates individual life cycles, the sequence of generations, and the structure of society simultaneously, for all three have evolved together.

Each person must translate this order into his own terms so as to make it amenable to whatever kind of trait inventory, normative scale, measurement, or educational goal is his main concern. Science and technology are, no doubt, changing essential aspects of the course of life, wherefore some increased awareness of the functional wholeness of the cycle may be mandatory. Interdisciplinary work will define in practical and applicable terms what evolved order is common to all men and what true equality of opportunity must mean in planning for future generations.

The study of the human life cycle has immediate applications in a number of fields. Paramount is the science of human development within social institutions. In psychiatry (and in its applications to law), the diagnostic and prognostic assessment of disturbances common to life stages should help to outweigh fatalistic diagnoses. Whatever will prove tangibly lawful about the cycle of life will also be an important focus for anthropology insofar as it assesses universal functions in the variety of institutional forms. Finally, as the study of the life history emerges from that of case histories, it will throw new light on biography and thus on history itself.

LIFE TABLES

The life table (also referred to as the mortality table) is a statistical device used to compute chances of survivorship and death and average remaining years of life, for specific years of age. The concept of the life table is applicable not only to humans (Spiegelman 1957) and other species of life (Haldane 1953; Ciba Foundation 1959) but also to items of industrial equipment (Dublin, Lotka, & Spiegelman [1936] 1949) and other defined aggregates subject to a measurable process of attrition. Life tables can also be developed further for computing the chances of other vital events in human life, such as marriage and remarriage, the birth of children, widowhood, illness and disability, and labor force participation and retirement (Spiegelman 1957); and they enter into a wide variety of annuity and life insurance computations (Hooker & Longley-Cook 1953-1957; Jordan 1952).

The conventional life table

The conventional form of a life table for the general population is illustrated in Table 1. The original data are recorded deaths and the census of population classified according to age (this step is not shown on the table). From these data were computed the *rates of mortality*, conventionally designated as q_x , for each year of age, x . These rates show the proportion of deaths occurring within the year of age among those who attain that age; the rates are usually shown per thousand (1,000 q_x). For example, Table 1 shows that of every 1,000 who just attained age 0 (the newly born), 23.55 died before reaching their first birthday; similarly, of every 1,000 who attained age six, 0.53 died within that year of age. Typically, mortality rates for a general population start at a high point in the first year of life, fall rapidly to a minimum at about age ten, and then rise with advance in years. The rise is gradual to about age 40, and then becomes increasingly rapid; since the maximum attainable age for human beings is in the neighborhood of 110 years, life tables seldom go beyond that point.

Once one knows the mortality rates at each age of life, it becomes possible to compute the number

of *survivors* (column l_x of the life table) and also the number of *deaths* (column d_x). It is usually most convenient to start the population life table with a base (radix) of 100,000 newborn individuals. In the example presented here, where there is a death rate of 23.55 per 1,000 at age 0, among the 100,000 newly born there must be 2,355 deaths in the first year of life. The number of survivors to attain age 1 is then $100,000 - 2,355 = 97,645$. With a mortality rate of 1.89 per 1,000 at age 1, among the 97,645 who attained that age there are

$$97,645 \times \frac{1.89}{1,000} = 185 \text{ deaths.}$$

The number of survivors to age 2 is then calculated in the same way:

$$97,645 - 185 = 97,460.$$

This procedure is continued to the end of the life table. Obviously, the number in the survivorship column, l_x , at any attained age is equal to the sum of the deaths in the d_x column for that and all higher ages.

To compute the *expectation of life* (e_x), or average future lifetime, for any attained age, it will be assumed that deaths, d_x , are uniformly distributed over the year of age, x . Equivalent to this is the

Table 1 — Life table for white females, United States, 1949–1951^a

Year of age	RATE OF MORTALITY PER 1,000		OF 100,000 BORN ALIVE		Number of years lived by the cohort between ages x and $x+1$	Total number of years lived by the cohort from age x on, until all have died	Average number of years lived after age x per person surviving to exact age x^b
	Number dying between ages x and $x+1$ among 1,000 living at age x	$1,000q_x$	Number surviving to exact age x	Number dying between ages x and $x+1$			
x			l_x	d_x	L_x	T_x	e_x
0	23.55		100,000	2,355	97,965	7,203,179	72.03
1	1.89		97,645	185	97,552	7,105,214	72.77
2	1.12		97,460	109	97,406	7,007,662	71.90
3	0.87		97,351	85	97,308	6,910,256	70.98
4	0.69		97,266	67	97,233	6,812,948	70.04

a. Based upon recorded deaths in the United States during the three-year period 1949–1951, recorded births for each year from 1944 through 1951, and the census of population taken April 1, 1950; for details, see U.S. Public Health Service 1959, pp. 149–158.

b. Represents complete expectation of life, or average future lifetime.

Source: U.S. Public Health Service 1954–1955, p. 18.

assumption that each of the persons dying lived one-half year after the last birthday. Thus, among the 294 in Table 1 who attained age 100, there were 114 deaths during that year of age, and these individuals lived $\frac{1}{2} \times 114$ years after their last birthday. Similarly, the 73 who died at age 101 lived $1\frac{1}{2}$ years each after attaining age 100, and the 46 who died at age 102 lived $2\frac{1}{2}$ years each after attaining age 100, and so on, to the last death. Altogether, the total number of years of life lived from age 100 on by the 294 who attained that age is $(\frac{1}{2} \times 114) + (1\frac{1}{2} \times 73) + (2\frac{1}{2} \times 46) + (3\frac{1}{2} \times 27) + \dots = 566$. This is the figure for age 100 in the column headed T_x . Since the 294 who attained age 100 lived a total of 566 years from their 100th birthday until the death of the last survivor, the average remaining lifetime was

$$566 \div 294 = 1.92 \text{ years.}$$

This is more commonly known as the expectation of life, e_x ; as an average, it is not applicable to any specific individual.

In Table 1 the life table symbols at the head of each column are defined by the terms above them. Reference has already been made to each, except L_x , which denotes the total number of years lived within the year of age by the number, l_x , who attain that age. It has been assumed that each of the persons dying lived only one half year after the last birthday. Accordingly, among the number, l_x , who attain age x , the years of life lived by those dying during that year of age is $\frac{1}{2}d_x$. The years of life lived by the survivors is l_{x+1} , which is equal to $l_x - d_x$. The sum of $\frac{1}{2}d_x$ and $l_x - d_x$ is the total number of years lived within that year of age. Thus,

$$L_x = l_x - \frac{1}{2}d_x.$$

Since T_x is the total number of years lived from age x on by those who attain age x , it follows that

$$T_x = L_x + L_{x+1} + L_{x+2} + \dots$$

and also that

$$T_x = L_x + T_{x+1}.$$

It should be recognized that except for the mortality rates, which represent an actually observed situation, all other columns of figures in the life table represent a hypothetical situation. Thus, the survivorship column and the column of life table deaths show only the expected number of survivals and deaths for successive ages, on the assumption that the mortality rates observed during the specified calendar period continue without change over

time. The same assumption underlies the column of figures for expectation of life.

Life table formulas. It will be seen from the preceding discussion that the construction of life tables rests upon a small number of elementary assumptions, which can be summarized in the following formulas:

$$l_x - l_{x+1} = d_x,$$

$$q_x = \frac{d_x}{l_x}.$$

Moreover, it is evident that if p_x denotes the probability of surviving one year after attaining age x , then

$$p_x = \frac{l_{x+1}}{l_x} = \frac{l_x - d_x}{l_x} = 1 - q_x.$$

Similarly, if ${}_np_x$ denotes the probability of surviving n years after attaining age x , then

$${}_np_x = \frac{l_{x+n}}{l_x} = 1 - {}_nq_x,$$

where ${}_nq_x$ is the probability of dying within n years after attaining age x . Thus,

$${}_nq_x = 1 - {}_np_x = \frac{l_x - l_{x+n}}{l_x}.$$

Another measure of mortality is the "force of mortality." This measure takes into account the fact that mortality varies continually with advance in age. In this sense, the rate of mortality in the brief instant after attaining exact age x will be different from that for the brief instant just before leaving age x to attain exact age $x + 1$. The force of mortality, μ_x , is the annual rate of loss of lives, corresponding to the loss, at any instant of time, per head surviving at that time. In terms of the calculus,

$$\mu_x = -\frac{1}{l_x} \cdot \frac{dl_x}{dx} = -\frac{d \log l_x}{dx},$$

where d/dx denotes the derivative of the specified function with respect to x .

The force of mortality at age x may be approximated by

$$\mu_x = \frac{l_{x-1} - l_{x+1}}{2l_x}$$

or, more closely, by

$$\mu_x = \frac{8(l_{x-1} - l_{x+1}) - (l_{x-2} - l_{x+2})}{12l_x}.$$

The relevant approximation formulas have been discussed by Jordan (1952, pp. 19-21).

Life table computation. The first task to be carried out in computing a life table for any specific population is to convert the *central death*

rate, m_x —that is, the average annual death rate for persons of a given age—into a *mortality rate*, q_x , such as has already been described. A means of doing this is illustrated as follows. In any specified community, let D_x denote the number of deaths recorded within a calendar year of individuals at age x on last birthday (or average annual deaths for a calendar period). Also, let P_x denote the number of people at age x on last birthday on the mid-date of the calendar year or period; this is an approximation to the average number living and, therefore, to the number of years of life lived within the year of age. Then the central death rate at age x for the community is

$$m_x = \frac{D_x}{P_x}.$$

The problem is to convert the central death rate, m_x , into a mortality rate, q_x .

In the life table the number of years of life lived during the year of age x is L_x and deaths during age x number d_x , so that the central death rate m_x is

$$m_x = \frac{d_x}{L_x} = \frac{d_x}{L_x - \frac{1}{2}d_x}.$$

Since $d_x = l_x \cdot q_x$,

$$m_x = \frac{l_x \cdot q_x}{L_x - \frac{1}{2}l_x q_x} = \frac{q_x}{1 - \frac{1}{2}q_x}.$$

Solving for q_x yields

$$q_x = \frac{m_x}{1 + \frac{1}{2}m_x}.$$

In terms of the recorded (observed) deaths and population,

$$q_x = \frac{D_x/P_x}{1 + \frac{1}{2}D_x/P_x} = \frac{D_x}{P_x + \frac{1}{2}D_x}.$$

In practice, however, the mortality rates at the very early ages are usually computed on the basis of a population estimated from recorded births and deaths, since census data for this stage of life are usually unreliable. The risk of mortality in infancy is highest in the first month following birth, and decreases rapidly thereafter; accordingly, the assumption of a uniform distribution of deaths is not valid for the first year of age. For the terminal ages of life, the basic data are usually meager and unreliable; various artifacts are therefore used to compute these mortality rates. The mortality rates for the broad range of intervening ages are generally subjected to mathematical procedures of interpolation and graduation in order to produce a smooth progression of figures (Spiegelman 1955, p. 72). A complete life table shows the figures in

each column for every age of life. An abridged life table shows figures for only selected ages, such as every fifth or tenth year of age.

Life tables directly from census data

Where death data are grossly inadequate or lacking, a life table may be approximated from the age distributions of population in two consecutive censuses, as in the following simplified example.

Assume two censuses, five years apart, with correct reporting of ages and with no migration. Then, clearly, the population at age $x+5$ in the second census, P''_{x+5} , consists of survivors of the population five years younger at the time of the first census, P'_x . The ratio of P''_{x+5} to P'_x accordingly is a five-year survivorship rate for a population at age x last birthday. Assuming a uniform distribution of population over the year of age, this population is approximately at an average attained age $x + \frac{1}{2}$. Thus,

$${}_5p_{x+\frac{1}{2}} = \frac{P''_{x+5}}{P'_x}.$$

Having arrived at a series of values of ${}_5p_{x+\frac{1}{2}}$ according to age, it is possible to work back to a series of mortality rates, q_x . In using this method, allowance may be made for migration (Mortara 1949).

There is also a method of life table estimation that can be used when a population age distribution is available from only one census (Stolnitz 1956). If there is good reason to believe that the size of the population of a community has been virtually stationary over time and that mortality according to age has remained essentially unchanged over time, then its age distribution is clearly very much like that of the life table column L_x . In other words, the number living, P_x , at age x last birthday is proportionate to L_x . Thus,

$${}_5p_{x+\frac{1}{2}} = \frac{P_{x+5}}{P_x} = \frac{L_{x+5}}{L_x},$$

and q_x may be estimated, as in the case with two consecutive censuses.

Consider now a population that may be regarded as stable, in the sense that it is growing at a constant annual rate, r , and that mortality at each age is also constant over time. This growth results solely from an excess of births over deaths each year; there is no migration. Then, for an interval of five years,

$$P''_x = P'_x(1+r)^5.$$

Likewise, P''_{x+5} consists of survivors of P'_x as before. It follows that

$${}_5p_{x+\frac{1}{2}} = \frac{P''_{x+5}}{P'_x} = \frac{P''_{x+5}}{P'_x/(1+r)^5} = \frac{P''_{x+5}(1+r)^5}{P'_x},$$

so that use is made of the population at the second census only. Stolnitz generalized this approach by tracing the populations P_{x+5}'' and P_x'' from their respective births, $x+5$ and x years previously, namely B_{x+5} and B_x . For this, he introduced survival factors to the same attained age x last birthday, namely S_x' and S_x'' , and made use of the five-year survivorship ratio, ${}_5p_{x+\frac{1}{2}}$. Thus,

$$\frac{P_{x+5}''}{P_x''} = \frac{B_{x+5}}{B_x} \cdot \frac{S_x'}{S_x''} \cdot {}_5p_{x+\frac{1}{2}}$$

Stolnitz shows how the birth ratio and the ratio of survival factors may be estimated from other experiences. With such estimates it becomes possible to compute ${}_5p_{x+\frac{1}{2}}$ from the age distribution of a single census.

Model life tables for developing areas. In the developing areas the problem is to estimate a life table for a population with scanty mortality data or from data gathered in a special survey. Since the mortality rate in infancy or the first few years of life is frequently indicative of the general level of mortality, such a rate may be used as the basis for estimation of life table values. Such an observed mortality rate, with suitable adjustment to enhance its validity, is used as a key to select one of a series of life table mortality rates (q_0 , q_1 , and q_x for x at five-year intervals) from 40 theoretical model series (United Nations 1955a). These models were derived from a study of the patterns of mortality rates in existing life tables. For refinement, the series of life table mortality rates may be selected by interpolating among the models on the basis of the key rate. Further refinement is possible by computing from the equations used to derive the models. Although these model life tables of the United Nations have been subject to technical criticisms,

they are widely used (Gabriel & Ronen 1958; Kurup 1966). A more extensive set of model life tables, prepared at Princeton University, takes into account variations in the patterns of mortality between four broad geographic regions, defined as East, West, North, and South, in addition to variations in the level of mortality within each region (Coale & Demeny 1966).

Life tables directly from death data

As pointed out before, in a population that is virtually stationary, with mortality rates essentially unchanged over time, the age distribution corresponds closely to that in a life table. Only in such a situation is it feasible to cumulate the distribution of deaths according to age, starting with the highest age and noting the total for each age, running back to birth, in order to approximate the survivorship column of the life table. This approach is not applicable in any other situation, since the age distribution of deaths will be influenced by the age distribution of the population. Thus, a population with a large proportion of aged persons will have a large proportion of its deaths at the older ages, irrespective of the level of its mortality rates.

Multiple decrement tables

In a multiple decrement table, the survivorship column of the life table is split, in passing from one age to the next, into two or more component parts, on the basis of changes in status or of newly acquired characteristics (Jordan 1952, pp. 237, 251; Bailey & Haycocks 1946). One example is the case where the survivorship column is split, on the basis of marriage rates according to age, to distinguish those who marry from those who remain single. In another example, shown in Table 2, the

Table 2 — Example of a double decrement table, with decrements by death and by disability

Year of age, x	RATE OF MORTALITY PER 1,000		DISABILITY RATE PER 1,000 ^b	Of 100,000 born alive ^a						
				NUMBER SURVIVING TO EXACT AGE x			ACTIVE LIVES DISABLED	NUMBER DYING BETWEEN AGES x AND $x + 1$		
	Among active lives	Among disabled lives	Among active lives	Total	As active lives	As disabled lives ^c	Between ages x and $x + 1$	Total	Among active lives	Among disabled lives

SELECT TABLE

ULTIMATE TABLE

Source: Adapted from Myers 1949, p. 73.

survivorship column of the life table is split to show those who become permanently disabled lives apart from those who remain as active lives. This table shows, in addition to the numbers surviving to successive ages as active lives and as permanently disabled lives, the rates of mortality for each of these categories and the rates at which active lives become permanently disabled. The column of life table deaths is also split to show the number of deaths among the permanently disabled separately from that among the active. It is assumed that the number of newly disabled lives in any year of age is uniformly distributed over that year; consequently, they are exposed to the mortality rate of the disabled for an average of one half of a year.

Select tables

The life table has been described in terms of rates of mortality dependent only upon attained age; in describing multiple decrement tables, reference was made to rates of disability and of marriage according to attained age. In select tables, rates of mortality (or other rates) are shown on the basis of both the age at acquisition of a new characteristic and the duration since that acquisition (Jordan 1952, p. 26). This two-way classification constitutes a select table, since some selective process is present at the time of acquisition. For example, mortality rates for permanently disabled lives may be shown not only for the age at which disablement occurred but also separately for each subsequent year of disability. Another example of a select table is the two-way classification of rates of remarriage for widows, in relation to both age at widowhood and years since that event. Such a two-way classification of rates is shown in Table 3. In that table, remarriage rates after the fifth year of widowhood are shown only on the basis of attained age, since duration in this case is only of minor influence upon the rates. The table as a whole is known as a select and ultimate table. That portion showing rates according to duration since

widowhood is the select table; the ultimate table is that portion showing rates only according to attained age, since duration is no longer of any importance. Select and ultimate tables are used in life insurance mortality investigations. The choice of the number of durations to be shown for the select period is a matter of study in each experience.

Cohort or generation life tables

In the foregoing account of the conventional life table and the related multiple decrement and select tables, the rates of mortality and other rates of attrition were based upon observations during some specified year or other period. The hypothetical nature of the conventional life table with respect to the time period of observation has already been indicated. A realistic picture of the mortality and survivorship experience of a cohort traced from birth is obtained by observing these events each year in a generation born at the latest 100 years ago. In that way, a record would be obtained of the number surviving to successive ages in successive years and also of the corresponding number of deaths at each age; the mortality rates according to age in successive years may then be computed. After the last death, it would be possible to compute the average length of life of the generation and the average years of life remaining after each age. Such a table is called a generation life table, since it reflects the actual mortality rates of a cohort as it ages in successive years. The table derived from mortality rates for a calendar year or period is called a current life table (Dublin, Lotka, & Spiegelman [1936] 1949, p. 174; Jacobson 1964). Thus, the expectation of life computed from mortality rates observed in 1850 will understate the average length of life of the generation born that year, because of the reductions in mortality since then. In general, with the trend toward lower mortality, the expectation of life at birth computed from a current life table understates the average length of life of a newly born generation.

Further applications

In addition to the applications of the life table that are mentioned in the opening paragraph of this article, increasing use is being made of it as an analytic tool in social and economic problems. Several interesting and important examples may be cited in the field of demography (for references to examples, see Spiegelman 1955; 1957). John Durand (1960) made use of the United Nations model life tables, cited previously, as an adjunct in arriving at estimates of expectation of life at birth for the western Roman Empire. The life table is fundamental in the stable-population theory developed by A. J. Lotka (Dublin & Lotka 1925) and also in Lotka's work on the structure of a growing population (1931). In the field of education E. G. Stockwell and C. B. Nam (1963) prepared school life tables to show the joint effects of death and school dropouts on school attendance patterns. B. C. Churchill (1955) studied the mortality and survival of manufacturing, wholesale trade, and retail trade firms in the United States; in similar fashion A. J. Jaffe (1961) has used data from the censuses of manufactures in Puerto Rico to prepare survival curves according to the age of the establishment.

BIBLIOGRAPHY

A very elementary account of the essentials of the life table is given in Dublin, Lotka, & Spiegelman [1936] 1949. A wholly nontechnical account of the life table, including double decrement and select tables, with brief descriptions of applications, will be found in Spiegelman 1957. The beginner in graduate study who has a nonmathematical background but a sense of arithmetic will find the chapter on the life table in Barclay 1958 a good introduction to the subject. A corresponding account of the life table, with some further development, is contained in Pressat 1961. U.S. Bureau of the Census 1951 provides step-by-step directions for elementary life table construction, as well as exercises for the beginning student. More technical is the exposition of the life table in Benjamin 1959. The student with a background in the calculus seeking a more comprehensive understanding of the life table, double decrement tables, and select tables may start with Hooker & Longley-Cook 1953-1957, Jordan 1952. The theoretical aspects of double and higher-order decrement tables are discussed in Bailey & Haycocks 1946. A firm understanding of the techniques of life table construction requires a good background in the means for estimating the exposed-to risk, as given in Gershenson 1961, and also for a grasp of the elements of graduation and interpolation, as given in Miller 1946. The principal techniques used in the construction of life tables are described in Spiegelman 1955, which also treats, in detail, the special situations at the early ages, where the assumption of a uniform distribution of deaths over the year of age is not applicable, and at extreme old age, where artifacts are used to complete the column of mortality rates.

LIFE TESTING

See under QUALITY CONTROL, STATISTICAL.

LIKELIHOOD

The likelihood function is important in nearly every part of statistical inference, but concern here is with just the *likelihood principle*, a very general and problematic concept of statistical evidence. [For discussion of other roles of the likelihood function, see ESTIMATION; HYPOTHESIS TESTING; SUFFICIENCY.]

The likelihood function is defined in terms of the probability law (or density function) assumed to represent a sampling or experimental situation: When the observation variables are fixed at the

values actually observed, the resulting function of the unknown parameter(s) is the likelihood function. (More precisely, two such functions identical except for a constant factor are considered equivalent representations of the same likelihood function.)

The likelihood principle may be stated in two parts: (1) the likelihood function, determined by the sample observed in any given case, represents fully the evidence about parameter values available in those observations (this is the *likelihood axiom*); and (2) the evidence supporting one parameter value (or point) as against another is given by relative values of the likelihood function (likelihood ratios).

For example, suppose that a random sample of ten patients suffering from migraine are treated by an experimental drug and that four of them report relief. The sampling is binomial, and the investigator is interested in the unknown proportion, p , in the population of potential patients, who would report relief. The likelihood function determined by the sample is a function of p ,

$$\binom{10}{4} p^4 (1-p)^6, \quad 0 \leq p \leq 1,$$

whose graph is shown in Figure 1. This likelihood function has a maximum at $p = .4$ and becomes very small, approaching 0, as p approaches 0 or 1. Hence, according to the likelihood principle, values of p very near .4 are supported by the evidence in this sample, as against values of p very near 0 or 1, with very great strength, since the corresponding likelihood ratios $(.4)^4(.6)^6/p^4(1-p)^6$ are very large.

Figure 1 — The likelihood function $\binom{10}{4} p^4 (1-p)^6$

A different rule for sampling patients would be to treat and observe them one at a time until just four had reported relief. A possible outcome would be that just ten would be observed, with six report-

ing no relief and of course four reporting relief. The probability of that observed outcome is

$$\binom{9}{3} p^4 (1-p)^6, \quad 0 \leq p \leq 1.$$

This function of p differs from the previous one by only a constant factor and hence is considered to be an alternative, equivalent representation of the same likelihood function. The likelihood principle asserts that therefore the evidence about p in the two cases is the same, notwithstanding other differences in the two probability laws, which appear for other possible samples.

Relation to other statistical theory. The likelihood principle is incompatible with the main body of modern statistical theory and practice, notably the Neyman-Pearson theory of hypothesis testing and of confidence intervals, and incompatible in general even with such well-known concepts as standard error of an estimate and significance level [see ESTIMATION; HYPOTHESIS TESTING].

To illustrate this incompatibility, observe that in the example two distinct sampling rules gave the same likelihood function, and hence the same evidence under the likelihood principle. On the other hand, different determinations of a lower 95 per cent confidence limit for p are required under the respective sampling rules, and the two confidence limits obtained are different. The likelihood principle, however, is given full formal justification and interpretation within Bayesian inference theories and much interest in the principle stems from recently renewed interest and developments in such theories [see BAYESIAN INFERENCE].

Finally, on grounds independent of the crucial and controversial Bayesian concepts of prior or personal probability, interest and support for the likelihood principle arises because most standard statistical theory fails to include (and clearly implicitly excludes) any precise general concept of evidence in an observed sample, while several concepts of evidence that many statisticians consider appropriate have been found on analysis to entail the likelihood axiom. Some of these concepts have become part of a more or less coherent widespread body of theory and practice in which the Neyman-Pearson approach is complemented by concepts of evidence often left implicit. Such concepts also appear as basic in some of Fisher's theories. When formulated as axioms and analyzed, these concepts have been discovered to be equivalent to the likelihood axiom and hence basically incompatible with, rather than possible complements to, the Neyman-Pearson theory.

General concepts of statistical evidence. The central one of these concepts is that of *condition-*

ality (or *ancillarity*), a concept that appeared first in rather special technical contexts. Another somewhat similar concept of evidence, which can be illustrated more simply here and which also entails the major part of the likelihood axiom, is the *censoring axiom*: Suppose that after interpretation of the outcome described with the second sampling rule of the example, it is discovered that the reserve supply of the experimental drug had been accidentally destroyed and is irreplaceable and that no more than ten patients could have been treated with the supply on hand for the experiment. Is the interpretation of the outcome to be changed? In the hypothetical possible case that seven or more patients reported no relief before a fourth reported relief, the sampling plan could not have been carried through even to the necessary eleventh patient: The change of conditions makes unavailable ("censored") the information whether if an outcome were to include more than six patients reporting no relief, that number would be seven, or eight, or any specific larger number. But in fact the outcome actually observed was a physical event unaffected, except in a hypothetical sense, by the differences between intended and realizable sampling plans. Many statisticians consider such a hypothetical distinction irrelevant to the evidence in an outcome. It follows readily from the general formulation of such a concept that the evidence in the observed outcome is characterized by just the function $\binom{9}{3} p^4 (1-p)^6, 0 \leq p \leq 1$. More generally this censoring concept is seen to be the likelihood axiom, slightly weakened by disallowance of an arbitrary constant factor; the qualification is removable with adoption of another very weak "sufficiency" concept concerning evidence (see Birnbaum 1961; 1962; Pratt 1961).

Interpreting evidence. The only method proposed for interpreting evidence just through likelihood functions, apart from Bayesian methods, is that stated as part (2) of the likelihood principle above. The briefness and informality of these statements and interpretation are typical of those given by their originator, R. A. Fisher (1925; 1956), and their leading proponent, G. A. Barnard (1947; 1949; 1962). "Likelihood ratio" appears in such interpretations as a primitive term concerning statistical evidence, associated in each case with a nonnegative numerical value, with larger values representing qualitatively greater support for one parameter point against the other, and with unity (representing "no evidence") the only distinguished point on the scale. But likelihood ratio here is not subject to definition or interpretation in terms of other independently defined extramathematical concepts.

Only in the simplest case, where the parameter space has but two points (a case rare in practice but of real theoretical interest), are such interpretations of likelihood functions clearly plausible; and in this case they appear to many to be far superior to more standard methods, for example, significance tests. In such cases the likelihood function is represented by a single likelihood ratio.

In the principal case of larger parameter spaces, such interpretations can be seriously misleading with high probability and are considered unacceptable by most statisticians (see Stein 1962; Armitage 1963). Thus progress in clarifying the important problem of an adequate non-Bayesian concept of statistical evidence leaves the problem not only unresolved but in a positively anomalous state.

Another type of argument supporting the likelihood principle on non-Bayesian grounds is based upon axioms characterizing rational decision making, in situations of uncertainty, rather than concepts of statistical evidence (see, for example, Cornfield 1966; Luce & Raiffa 1957).

Likelihoods in form of normal densities. Attention is sometimes focused on cases where likelihood functions have the form of normal density functions. This form occurs in the very simple and familiar problem of inferences about the mean of a normal distribution with known variance (with ordinary sampling). Hence adoption of the likelihood axiom warrants and invites identification with this familiar problem of all other cases where such likelihood functions occur. In particular, the maximum likelihood estimator in any such case is thus related to the classical estimator of the normal mean (the sample mean), and the curvature of the likelihood function (or of its logarithm) at its maximum is thus related to the variance of that classical estimator. In similar vein, transformations of parameters have been considered that tend to give likelihood functions a normal density shape (in problems with several parameters as well as those with only one). (See, for example, Anscombe 1964.)

Likelihoods in nonparametric problems. In nonparametric problems, there is no finite set of parameters that can be taken as the arguments of a likelihood function, and it may not be obvious that the likelihood axiom has meaning. However, "nonparametric" is a sometimes misleading name for a very broad mathematical model that includes all specific parametric families of laws among those allowed; hence in principle it is simple to imagine (although in practice formidably awkward to represent) the extremely inclusive parameter space containing a point representing each (absolutely) continuous law, and for each pair of such

points a likelihood ratio (determined as usual from the observed sample).

LIMITED WAR

Limited war is a subjective and relative term that has gained currency chiefly to distinguish certain conflicts from wars fought for ends and by means that have impressed men as extreme. Limited wars are as old as the history of mankind. They

have occurred among the most primitive and the most advanced peoples and in every civilization. The great majority of all international wars have been fought for ends far short of domination or annihilation and by means far short of the complete destruction of the enemy's armed forces or his society. In these respects even the two so-called total wars of this century—World War I and World War II—were significantly limited.

The concept of limited war is also old and ubiquitous in history. Primitive tribes, as well as the knights of the Middle Ages, have been conscious of explicit customs and rules of mutual restraint in the conduct of warfare. In ancient China, as well as eighteenth-century Europe, there were laws explicitly formulated to regulate warfare.

Yet the consciousness of limited war as a distinct kind of warfare, with its own theory and doctrine, has emerged most markedly in contrast to three major wars, waged between several major states, in behalf of popular national and ideological goals, by means of organized conscripted forces and massive firepower: the Napoleonic Wars, World War I, and World War II.

The detailed elaboration of a strategic doctrine of limited war, the formulation of specific plans for carrying out this doctrine, and the combined efforts of government, the military establishment, and private analysts and publicists to translate the doctrine into particular weapons and forces are developments peculiar to the nuclear age. They are products of the profound fear of nuclear war and the belief that the limitation of war must be carefully contrived, rather than left to inherent limitations upon military capabilities.

The principal exponents of limited war in the eighteenth century were (1) the principal military tacticians of wars of fortification and maneuver, like Vauban and Marshal de Saxe; (2) proponents of international laws to regulate and civilize war, like Vattel, who drew upon the principles of Grotius; and (3) political theorists like Rousseau and Fénelon, who saw war as a necessary, if rather indecisive, instrument for preserving a balance of power. In the latter half of the nineteenth century legal and balance-of-power theorists were somewhat overshadowed by the exponents of modern military power and glory, like Marshal Foch. Most of the leading military thinkers, with the notable exception of Karl von Clausewitz, were prophets of blitzkrieg and wars of annihilation. After World War I, proponents of international order, in their search for collective security and disarmament as methods of avoiding war, generally ignored the problem of limiting war. Liddell Hart, virtually the only exponent of a military strategy of limited war

between the two world wars, applied his prescriptions chiefly to Britain's situation.

After World War II, however, there was a great resurgence of interest in limited war among civilian analysts as well as military experts, particularly in the United States after the Korean War. The new exponents of limited war advocated the systematic control of military potential and of war as a useful, carefully restricted instrument of policy. On the most fundamental level they drew their inspiration from Clausewitz, who in expounding the theory of war as a continuation of diplomacy had related the scope and intensity of war to its political context with a profundity appreciated equally by Lenin and Mao Tse-tung. [See the biography of CLAUSEWITZ.]

A limited war is now broadly defined as a war that is fought for ends far short of the complete subordination of one state's will to another's and by means involving far less than the total military resources of the belligerents, leaving the civilian life and the armed forces of the belligerents largely intact and leading to a bargained termination. More narrowly, it is defined as a local nonnuclear war. Limited war is therefore a matter of degree. It is also a matter of perspective, since a war that is limited for one belligerent might be close to total for another. Furthermore, a limited war may be restricted in some respects and not in others. Thus, a civil war or insurrection may be fought by limited means for the total stake of controlling a government.

Yet despite the impossibility of defining limited war by simple and absolute criteria, it is not difficult, historically, to distinguish limited wars from wars of great scope and intensity.

Limited wars in history

The eighteenth century. The middle of the eighteenth century stands out as the first notable period of limited warfare in the history of the modern state system. In marked contrast to the preceding religious wars and the general wars revolving around Louis XIV's struggle for hegemony and to the subsequent French Revolution and Napoleonic Wars, the wars of this period generally consisted of short, duellike battles of maneuver fought for limited dynastic and territorial objectives, within a system where rough equilibrium of power was maintained by about five major states. The wars left civilian life relatively unaffected and altered the international status of the major countries only minimally or gradually.

The limited character of war in this period must be attributed largely to the economic and technological obstacles preventing the major states from destroying each other's armed forces and devastat-

ing or occupying each other's homelands. This in turn reflected the limited capacity of monarchies to organize armed forces and mobilize military potential. Furthermore, warfare was limited by the great role of sea power and by the fact that sea war did not ravish the land.

The limited warfare of the eighteenth century, however, cannot be attributed solely to the nature of military technology, since the technology was not very different then from that of the preceding and following periods of general war. It must also be attributed to the limited nature of the political ends for which states fought; to the equilibrium of power between the major participants, which restrained them from pushing an advantage too far; to the stilted, drill-field military tactics suited to keeping expensive and untrustworthy troops under control; to a general respect for laws of war distinguishing between combatants and noncombatants, belligerents and nonbelligerents; and to the prevailing social and political system, which made these political, legal, and military constraints congenial to the homogeneous ruling classes of Europe. Beyond these factors, the limitation of eighteenth-century warfare can be explained simply by the desire of rulers and ruled to avoid the chaos of the religious wars.

The nineteenth century. The Napoleonic period removed many of the political and social conditions of limited war. In undermining the *ancien régime* and introducing the concept of the "nation in arms," it prepared the way for a popular nationalism far less congenial to the limitation of war than the pragmatic *Realpolitik* of the eighteenth century.

Napoleon demonstrated the capacity of states to generate popular enthusiasm for war by nationalistic and ideological appeals and to translate this enthusiasm into unprecedented military power through mass conscription and the mobilization of industry and technology. By reconciling military discipline with individual initiative, he enabled states to use new tactics of camouflage, mobility, and destructive pursuit that gave war a new dynamism. He showed that where such decisive force could be exerted on land, sea war would cease to be a limiting factor and instead would become, through blockade and the destruction of commerce, a forerunner of total war against civilian life.

Nevertheless, the rest of the nineteenth century—notably from 1854 to 1870—was, again, a period of limited war, thanks largely to the absence of wars between the several major states (except the Crimean War, which was fought in a peripheral location). The latter half of the nineteenth century saw the unprecedented development in peacetime

of war plans, conscription, military logistics, and communications (notably railroads and telegraph) and a rapidly advancing military technology. Yet, the new potentialities of destruction inherent in these developments were not fully exploited or generally appreciated until World War I, although the American Civil War should have been a grim warning. Instead, Prussia's quick, limited victories in 1866 (against Austria) and 1871 (against France) were believed to be the models of future wars.

The two world wars. World War I was not deliberately undertaken as a general war. It became a world war because of diplomatic miscalculations, the interlocking network of alliance commitments, the inflexibility of mobilization plans and war plans, the prevailing assumption among the military that a general war was inevitable, the weakness of civilian control over the military, and the failure of the initial German offensive, followed by a war of attrition and stalemate that national animosities, fed by popular sentiment, made it difficult to terminate without victory. Consequently, even if the will to avoid general war had been stronger, war would have become general and extremely destructive without a systematic effort by governments to subject military planning and operations to over-all political direction under a strategy of limited war.

Yet few drew any such lessons from that shocking experience. Rather, it was generally assumed that unless war could be avoided by collective security and disarmament there would soon be another and even more devastating world war. The rise of the expansionist totalitarian powers, the fascist glorification of war, and the perfection and proliferation of more destructive weapons, including aerial bombardment, seemed to make this inevitable.

Actually, the fascist states preferred to satisfy their ambitions through intimidation and through quick, limited aggressions against negligible opposition; but the failure of the democratic states to contain these aggressions at the outset by limited means and their unwillingness to use force for limited ends assured the fulfillment of the prophecies of total war when the democratic states, contrary to Hitler's calculations, belatedly offered resistance in 1939 and when Japan, confronted with the American oil embargo and rearmament, launched what it regarded as a limited, preventive attack on Pearl Harbor. ■

The nuclear age. In the aftermath of World War II, the invention of nuclear weapons and the onset of the cold war raised a general feeling that only the United Nations and disarmament could prevent another total war. Yet, within a decade

this opinion had been modified by the widespread conviction that the potential destructiveness of a nuclear war would deter a total war and by a concomitant surge of private and official interest in meeting a purported danger of limited wars.

This new attention to limited war has been justified by the occurrence of more than fifty limited wars of various kinds within twenty years after World War II. All of them were fought outside Europe, with the exception of the Greek civil war in 1945-1949 and the Hungarian rebellion in 1956. The great majority were internal wars; that is, wars that arose and were fought largely within the boundaries of a single state. Several of these were full-scale civil wars: in Greece; China in 1945-1949; Bolivia in 1949; Algeria in 1954-1962; Cuba in 1958-1959; the Congo in 1960-1963; Vietnam from 1959; and Indonesia in 1966.

A number of internal wars were, in communist parlance, "national liberation wars," supported from outside by the Soviet Union, Communist China, or other communist countries: in Greece; French Indochina in 1946-1954; Burma in 1948-1954; Malaya in 1948-1960; the Philippines in 1946-1954; and Vietnam. And one should add to this list two abortive rebellions against Soviet and Communist Chinese domination: in Hungary, and Tibet in 1956-1957. Although internal, most of these wars were major international political events because they determined the status of colonial holdings and/or affected the balance of power in the cold war.

Several of the approximately fifty limited wars arose from a direct invasion of the territory of one state by another state: the Korean War in 1950-1953; the Guatemalan war in 1954 (which, however, had many characteristics of an internal war); the Israeli-Egyptian war and the British-French invasion of Suez in 1956; and the Indian conquest of Goa in 1961. One might also categorize the Quemoy-Matsu conflict in 1954-1958 as an aborted interstate war. Like most of the internal wars, these interstate wars reflected the major political issues in the world since World War II: the national-colonial conflict and the communist-noncommunist conflict.

There were, also, a few interstate wars fought primarily by subversive means, but all of these except the war in Vietnam were low-level conflicts arising from indigenous national rivalries: Somalia-Ethiopia in 1960, Indonesia-Malaya in 1963, and Algeria-Morocco in 1963.

Some of the civil and internal wars were quite destructive—as in Greece, China, and Algeria—and total, rather than limited, in the sense that different regimes competed for complete control of

a country. The Korean War, although limited from the American and Chinese standpoint, was virtually total from the standpoint of the North and South Korean regimes. Yet, all of these wars were strictly limited in geographical extent, the number of countries directly involved, and the scope and intensity of violence. Although a number of them involved either the United States or the Soviet Union, none involved both powers directly and simultaneously.

The limited nature of these wars can be partly explained by a variety of conditions that helped limit wars in previous periods of history: the limited or local nature of political issues at stake, the tactics of internal warfare, the limited military capacity of the belligerents, the one-sided nature of the contest, the pressure by allies for constraint, the fear of overcommitment at the expense of protecting prior interests elsewhere. The notable feature of this period, however, is that despite the global nature of the cold war and the depth and intensity of the over-all conflict of interests and aims, and despite the immense destructive power that the principal adversaries could inflict upon each other, the major communist and democratic powers did not bring their full military power to bear upon each other. Only in the Korean War did major Western and communist powers employ their armed forces in direct combat with each other. Therefore, the limitation of warfare since World War II must be largely attributed to the military abstinence and restraint practiced by the principal adversaries in the cold war.

A large part of the explanation of this military abstinence and restraint lies in the deterrent effect of the very capacity for mutual destruction that would make another general war so catastrophic. This deterrent effect, combined with a number of other military and political factors conducive to limitation, was most marked in the Korean War, where, contrary to all previous expectations in the West, an American-Communist Chinese conflict remained local and limited, with each side deliberately refraining from military actions that threatened to expand the war and both sides agreeing to an inconclusive termination.

The limited war in Vietnam is as notable an example as the Korean War of studied application by the United States of ascending gradations of limited force toward the achievement of a negotiated settlement on limited terms. It was even more notable, however, for evoking widespread popular approval of and insistence upon such limits.

The modern concept

The Korean War in time stimulated a new concept and strategic doctrine of limited war, which

received additional impetus from the growth of Soviet nuclear striking power, the introduction of thermonuclear bombs and long-range missiles in Soviet and American arsenals, and the communists' explicit emphasis in the 1960s on national liberation wars.

According to this concept, the stability of the bipolar nuclear balance, resulting from the reluctance of the nuclear powers to use nuclear weapons except in retaliation against nuclear weapons, could not be relied upon to deter communist powers from supporting limited aggressions and might, in fact, encourage such aggressions because the United States might be deterred from using nuclear weapons first when it had no effective means of conventional resistance. Furthermore, if involved in a local conventional conflict, the United States and its allies might not be capable of controlling the escalation or expansion of such a war but would have to choose between defeat and a nuclear catastrophe. To deter such aggressions or to fight local wars effectively without incurring an intolerable risk of nuclear war, the United States, according to this thesis, would have to develop a capacity to fight different kinds of small wars successfully, with a diversified arsenal of conventional capabilities appropriate to various constraints upon weapons, targets, and the zone of combat, while holding open the lines of diplomatic communication to facilitate the termination of combat, probably short of a clear-cut military or political victory. This new concept of limited war was explicitly based on the principle, drawn from Clausewitz, that the conduct of war should be scrupulously disciplined by over-all political considerations, so that war will be an effective instrument of policy rather than an instrument of maximum destruction.

The concept of limited war did not find official favor with American Secretary of State Dulles; only in the last years of the Eisenhower administration were some concessions made to the idea. Instead, the administration stressed the alleged economic and military necessity of avoiding future Koreas by depending primarily on the American capacity to meet local conventional aggressions with strategic and tactical nuclear retaliation to deter little and big wars alike. This strategy—loosely called massive retaliation—was also adopted by allies of the United States in the North Atlantic Treaty Organization (NATO), who were equally anxious to substitute nuclear firepower for conventionally armed man power following their brief rearmament effort during the Korean War period.

In this period, however, a movement for strategic revision arose within the United States Army and Navy and among academic analysts and research

organizations interested in military questions. According to this revisionist movement, the dependence of the West on nuclear weapons was increasingly incredible as a deterrent against the most likely forms of aggression; it would be ineffective or disastrous if deterrence should fail or be inapplicable; and it was inadequate as an instrument of policy in conflicts short of war (in which the Soviet Union could confront the United States and its allies with the choice between acquiescence and thermonuclear holocaust).

When President Kennedy and Secretary of Defense McNamara took office in 1961, they explicitly adopted the concept of limited war, which had emerged as a criticism of the prevailing strategy. Moreover, they instituted a far-reaching program to revise military policies so as to support a strategy of limited war. They created "special forces" to handle guerrilla warfare, urged a build-up of NATO's conventional capabilities in order to raise the threshold of effective resistance without resorting to nuclear war, and increased the capacity of the United States to transport armed forces by air to prevent or deter local wars. The key phrase used to describe this revised strategy was "flexible and controlled response."

The concept of flexible and controlled response, however, was applied beyond local nonnuclear war. It also embraced the concept of deliberately planning for the "option" of using nuclear weapons in a limited fashion, under constraints upon their number, type, and targets and in response to effective central political direction. Thus, the concept of limited war came to include even a controlled strategic "counterforce" war, in which the United States would try to confine nuclear exchanges to such military targets as missile bases, holding back its capacity to devastate Soviet cities, as an inducement to the Soviet Union not to attack American cities.

Whether or not a nuclear war could be kept limited, the unwillingness of the American government to relinquish this possibility was a striking indication of growing inhibitions against resorting to unlimited war or depending entirely on the "balance of terror" to deter armed conflict. It signified increasing reluctance to depend for deterrence upon a military response that it would not be rational to carry out.

There were signs that the nuclear-missile age had induced similar attitudes in Soviet civilian and military leaders. Premier Khrushchev led Soviet spokesmen in avowing that thermonuclear weapons, by deterring the "capitalist-imperialist" powers, had overruled the Marxist-Leninist dictum that the dictatorship of the proletariat could come about

only by a violent clash of arms precipitated by imperialist desperation. Such a clash, he said, was no longer "fatalistically inevitable." On numerous occasions he and other Soviet leaders stressed the immense and intolerable damage that communist as well as "imperialist" powers would suffer in a nuclear war.

Although Chinese spokesmen did not disagree with this view, they differed with Soviet spokesmen in being more confident that the United States would be deterred by Soviet nuclear power from escalating national liberation wars and particularly from initiating the use of nuclear weapons.

Whether for effect or out of conviction, Soviet spokesmen continued to assert that any war between the Soviet Union and the United States would result in nuclear war and continued to deny the possibility that either a strategic or tactical nuclear war could be limited, but in the mid-1960s some Soviet military men began to publish criticisms and qualifications of these views.

Furthermore, communist doctrine had always emphasized political constraints on war and the cautious, flexible use of force. Mao Tse-tung's strategy of revolutionary war, which dominated Chinese thinking and remained the leading rationale of unconventional war, was suffused with concepts of limited war although its aim was total. By 1961 both Soviet and Chinese strategy emphasized the necessity of supporting "national liberation wars" (that is, internal wars promoting a communist takeover) and acknowledged the possibility of "local wars" outside Europe (that is, geographically restricted wars between states, which might or might not be limited in weapons) as a contingency to be deterred or frustrated.

Continuing problems

In the United States there emerged during the 1960s a broad consensus supporting the strategy of flexible and controlled response. America's European allies largely accepted the strategy as it applied outside Europe, but they were generally far more skeptical about the feasibility or utility of fighting a limited conventional war, let alone a limited nuclear war, in Europe. Their skepticism reflected differences of geography and was not likely to yield to American persuasion. Accordingly, they remained reluctant to build up NATO's conventional capabilities and were fearful that the emphasis on a strategy of limited conventional war would undermine the credibility of nuclear deterrence. France went furthest in openly criticizing the doctrine of flexible and controlled response and in acclaiming a doctrine of extended nuclear deter-

rence as a substitute for conventional resistance. Despite the German Federal Republic's twelve divisions and the six American divisions, the capacity of NATO's European-based forces to withstand the Soviet Union's forces in eastern Europe for more than a few days remained in doubt. France's withdrawal from NATO's integrated commands in 1966 only highlighted this situation.

The United States in the mid-1960s became increasingly preoccupied with the war in Vietnam. There the addition of concentrated firepower (including heavy strategic and tactical bombing) and regular ground warfare to guerrilla warfare and civic action fitted none of the previous concepts of limited war. Except for more detailed attention in the United States to the process of escalation, strategic thought about limited war seemed to have passed its phase of innovation.

Strategic quiescence, however, did not resolve outstanding differences in the West about the particular forces and strategies needed for deterrence, resistance, and the support of policy in crises short of war. What should be the purpose of NATO's conventional forces in Europe: to provide merely a "screening force" to detect an attack or to be a "tripwire" to sound the alarm for nuclear retaliation? to prevent an unopposed limited territorial grab? to force the enemy to pause long enough to consider the risk of a nuclear war? to withstand Soviet forces in Europe conventionally for days? months? Under what conditions, if any, should the West use nuclear weapons first? If nuclear weapons were used, how, if at all, could a bilateral nuclear war, especially one in Europe, be significantly limited in geographical extent, targets, and duration? What should be the function of tactical (that is, battlefield) weapons as opposed to longer-range nuclear weapons? Could either tactical or strategic nuclear exchanges be confined to "bargaining and demonstration"? How could such exchanges be kept under effective central command and political control?

The most hopeful thing about these unanswered and necessarily conjectural questions was that their very imponderability made a potential aggressor uncertain about the response to his incursions, and this uncertainty, combined with his awareness of the intolerable penalties of miscalculation, would itself be a powerful deterrent to rash moves. Indeed, notwithstanding the Korean War, throughout the cold war both the communist powers and the United States and its allies have exercised great caution in avoiding a direct military encounter with each other, afraid that any such encounter might expand into a thermonuclear war. Approaches to

the brink of war, such as the Formosa Strait crisis in 1958, the Berlin crises in 1948–1949 and 1958–1962, and the Cuban crisis in 1962, show that this caution does not preclude dangerous tests of will and nerve, under the shadow of war. Yet, through such tests the major adversaries in the cold war seem to have learned the acceptable limits of pressure and counterpressure short of war. If the *détente* that developed after the Cuban missile crisis should last, it will be largely due to this mutual understanding, toward which the American doctrine and forces of limited war made a major contribution by bolstering American resolve to accept the risks of war in crises.

One of the serious questions for the future, however, is whether the deterrents that have developed in an essentially bipolar world would persist in a world in which there might be a number of additional significant centers of political decision and military power both inside and outside the two blocs. A more decentralized structure of international power and interests might weaken the existing deterrents against aggression and war and increase the danger of limited wars breaking out and expanding into major wars, especially if the initial belligerents owned nuclear weapons. In the light of this danger, the most challenging problem of limiting warfare in the future might be to extend to an eroding bipolar or multipolar world methods and concepts of deterring, confining, and restraining warfare that would be as effective as those that emerged in the first two decades after what one must hope was the last, and not just the latest, world war.

LINDSAY, A. D.

Alexander Dunlop Lindsay, Lord Lindsay of Birker (1879–1952), a political philosopher, was born in Scotland but spent most of his life in England as fellow and then as master of Balliol College, Oxford. After his retirement, he became the first principal of the University College of North Staffordshire (now the University of Keele). Because of his services to the Trades Union Congress and the Labour party, he was elevated to the peerage in 1945 and took the title of Baron Lindsay of Birker. In many ways, Lindsay's life followed the pattern originated by such Oxford idealist philosophers as T. H. Green; in other ways, he followed the lead of Benjamin Jowett, perhaps the most famous of Lindsay's predecessors as master of Balliol. Like Green, he attempted to combine the teaching of philosophy with the obligations imposed by citizenship—participation in actual administration as well as aiding the poor and teaching the disadvantaged; like Jowett, he thought that the first purpose of a university is to train public servants by sharpening their intellects and developing

their will to control events. Lindsay also continued Balliol's Victorian tradition in that he preached in the college chapel and derived his politics as much from religion as from philosophy.

In the face of the assaults upon idealism made by Bertrand Russell, G. E. Moore, and Ludwig Wittgenstein, who redirected philosophical inquiry, Lindsay tacitly abandoned the traditional idealist attempt to base political ideas upon firm metaphysical grounds (for his specific criticism of modern British philosophy, see Lindsay 1951). Rather, he paraphrased idealist political ideas in terms derived from common sense, practical politics, and the language of classical political theory. The result was a persuasive statement of the "operative ideals" of modern constitutional democracies. Although Lindsay's work added little to what had already been said by Green and Bosanquet, he did prolong their influence by his restatement, which he based upon the points that had originally persuaded many people of the superiority of idealism over Victorian positivism and scientism, whether of the utilitarian or the social Darwinian varieties. As Talcott Parsons has indicated, idealism was an important source of modern sociology and political science. Idealist philosophers emphasized the importance of human groups, of collective representations, and the place of values in social action. No less important were idealist polemics against theories of human behavior that stress individual decisions taken on purely rational and self-interested grounds.

Lindsay's antipathy to doctrines stressing egotism was rooted in his family background. Both his parents were descended from Scottish families, aristocratic in origin but active in social work and in movements for the reform of religion and politics. His father was T. M. Lindsay, a distinguished church historian and principal of the United Free Church College at the University of Glasgow. Lindsay's first degree was from Glasgow University. Despite his failure to win a Snell exhibition at Balliol, he obtained a first class degree in greats and was elected president of the Oxford Union. Even as an undergraduate he was a member of the Fabian Society. After holding fellowships in philosophy at Glasgow and Edinburgh and assisting Samuel Alexander, professor of philosophy at Manchester, Lindsay was elected in 1906 to a fellowship at Balliol. In the period before World War I, he translated Plato's *Republic* (1907), wrote a number of prefaces to philosophical volumes in the Everyman's Library series, published short books on Henri Bergson (1911) and Kant (1913), and contributed to the influential volume, *Property: Its Duties and Rights* (1914), published by the Christian Social Union, an organization led by those of

Green's students who combined high-church theology with distaste for economic inequality. Lindsay married in 1907 and had two sons and a daughter.

After his service in World War I, Lindsay returned to Balliol and took an important part in establishing the new undergraduate degree in philosophy, politics, and economics. In 1922 he was elected professor of moral philosophy at Glasgow but returned to Oxford when he was elected master of Balliol in 1924. Although increasingly drawn into administration and university politics (he served a term as vice-chancellor of Oxford), he taught philosophy and preached in the Balliol chapel. Lindsay was among the few heads of Oxford colleges who supported the Labour party (1949). Probably the cause he cared for most was the Workers' Educational Association. In 1939 he was the Labour party candidate for a seat in Parliament that was won by Quinton Hogg, who had defended the Munich settlement of the previous year. During World War II, Lindsay often spoke on the radio and finished the first and, as it turned out, the only volume of his *Modern Democratic State* (1943), a work that displayed him at his best and was certainly preferable to his long book on Kant (1934a). After retiring as master of Balliol in 1948, he did much as first principal at Keele to institute a curriculum that put its stress on general education rather than on the specialized studies that until then were characteristic of English universities.

Lindsay's conception of political theory depended upon a series of distinctions that was designed to maintain the autonomy and, indeed, the primacy of ideas and values in the analysis of political action. Retreating from the metaphysical arguments of idealism, he nevertheless denied that the study of politics should center exclusively upon actual institutions or behavior. For Lindsay claimed that his position was neither metaphysical nor historical. He rejected the distinction between the state as studied by political theorists (in the form it ideally should have) and the state as studied by political scientists (in its actual form). Lindsay argued that these two views of the state are analytically and empirically inseparable.

Every state, he thought, is a historically conditioned association whose members share certain purposes, although these purposes need not be consciously recognized or fully realized. The laws, institutions, and moral and political practices of a society record its "operative ideals," that is, what it most values in its common life. Such preferences will be found to vary in the different historical types of states, such as the classical Greek democracies or medieval constitutional monarchies. What,

in Lindsay's view, distinguishes the modern democratic state from all other types is the fact that in it the political organization that exercises a monopoly of organized force has as its function neither the creation of operative ideals nor their enforcement by coercion alone. The power of the state is properly used when, and only when, it corrects anomalies and harmonizes conflicts. The purpose of the state is to remove hindrances to the kinds of spontaneity and freedom that are compatible with the common purposes of society. It is significant that when Lindsay made this central argument in his two major works (1929; 1943) he did so by paraphrasing Bosanquet:

What Bosanquet seems to have done in his account of the general will is to have developed a hint of Rousseau's into a masterly account of the elaborate system of institutions and mutual relations which go to make up the life of society, to have insisted on its complexity and richness and vitality, its transcendence of what any one individual can conceive or express. This, he declares, in all its elaborateness and multifariousness is the community. It is less than that. That is the standard of legislation and what we ordinarily call state action. The business of politics is to take this elaborate complex of individuals and institutions for granted . . . and . . . [to] seek to remove the disharmonies which are threatening its life and checking its vitality. ([1943] p. 244 in 1947 edition)

The state, in the narrow political sense, is, according to Lindsay, the hinderer of hindrances. The aim of its compulsion and the criterion of the success of that compulsion is the setting free of the spontaneity which is inherent in the life of society. Political machinery, general elections, legislatures, judges, and executives are endeavoring or ought to be endeavoring to express the spirit of a common social life.

Thus, Lindsay accepted certain distinctions that Bosanquet also had considered essential: the distinction between state and society, with primacy given to society; and that between the state, as an organization to which all must belong, and voluntary societies. These voluntary societies, traced by Lindsay to Puritan congregations, have the great merit of permitting individuals to have, within a limited sphere, real initiative, spontaneity, and liberty. But in the nature of things all such associations have purposes limited to the interests of their members. Voluntary associations, if left to themselves, come into conflict. It is the purpose of the state to eliminate such conflicts and to reconcile disagreements by reference to the operative ideals of society.

Lindsay, then, followed earlier idealists in a number of ways: he attempted to rescue by paraphrase and dilution a position that was essentially

religious; he favored reconciliation and synthesis of the interests of different groups, rather than the admission of persisting conflicts and harsh choices between such interests; he refused to distinguish fact from value and argued that the social arrangements and moral practices of a society provide a meaningful guide to future decisions, both by conscientious individuals seeking to determine their obligations and by the state seeking to determine the proper sphere of its action. From this mode of analysis, however, Lindsay drew socialist conclusions, thus distinguishing his position from those of Green and Bosanquet.

LINEAR HYPOTHESES

- I. REGRESSION
 II. ANALYSIS OF VARIANCE
 III. MULTIPLE COMPARISONS

E. J. Williams
 Julian C. Stanley
 Peter Nemenyi

I
 REGRESSION

Regression analysis, as it is presented in this article, is an important and general statistical tool. It is applicable to situations in which one observed variable has an expected value that is assumed to be a function of other variables; the function usually has a specified form with unspecified parameters. For example, an investigator might assume that under appropriate circumstances the expected score on an examination is a linear function of the length of training period. Here there are two parameters, slope and intercept of the line. The techniques of regression analysis may be classified into two kinds: (1) testing the concordance of the observations with the assumed model, usually in the framework of some broader model, and (2) carrying out estimation, or other sorts of inferences, about the parameters when the model is assumed to be correct. This area of statistics is sometimes known as "least squares," and in older publications it was called "the theory of errors."

In the regression relations discussed in this article only one variable is regarded as random; the others are either fixed by the investigator (where experimental control is possible) or selected in some way from among the possible values. The relation between the expected value of the random variable (called the dependent variable, the predictand, or the regressand) and the nonrandom variables (called regression variables, independent variables, predictors, or regressors) is known as a regression relation. Thus, if a random variable Y , depending on a variable x , varies at random about a linear function of x , we can write

$$Y = \beta_0 + \beta_1 x + e,$$

which expresses a linear regression relation. The parameters β_0 and β_1 are the regression coefficients or parameters, and e is a random variable with expected value zero. Usually the e 's corresponding to different values of Y are assumed to be uncorrelated and to have the same variance. If η denotes the expected value of Y , the basic relation may be expressed alternatively as

$$E(Y) = \eta = \beta_0 + \beta_1 x.$$

The parameters in the relation will be either unknown or given by theory; observations of Y for different values of x provide the means of esti-

imating these parameters or testing the concordance of the simple linear structure with the data.

Linear models, linear hypotheses. A regression relation that is linear in the unknown parameters is known as a linear model, and the assertion of such a model as a basis for inference is the assertion of a linear hypothesis. Often the term "linear hypothesis" refers to a restriction on the linear model (for example, specifying that a parameter has the value 7 or that two parameters are equal) that is to be tested. The importance of the linear model lies in its ease of application and understanding; there is a well-developed body of theory and techniques for the statistical treatment of linear models, in particular for the estimation of their parameters and the testing of hypotheses about them.

Needless to say, the description of a phenomenon by means of a linear model is usually a matter of convenience; the model is accepted until some more elaborate one is required. Nevertheless, the linear model has a wide range of applicability and is of great value in elucidating relationships, especially in the early stages of an investigation. Often a linear model is applicable only after transformations of the independent variables (like x in the above example), the dependent variable (Y , above), or both [see STATISTICAL ANALYSIS, SPECIAL PROBLEMS OF, article ON TRANSFORMATIONS OF DATA].

In its most general form, regression analysis includes a number of other statistical techniques as special cases. For instance, it is not necessary that the x 's be defined as metric variables. If the values of the observations on Y are classified into a number of groups—say, p —then the regression relation is written $E(Y) = \beta_1 x_1 + \beta_2 x_2 + \dots + \beta_p x_p$, and x_i may be taken to be 1 for all observations in the i th group and 0 for all the others. The p x -variables will then specify the different groups, and the regression relation will define the mean value of Y for each group. In the simplest case, with two groups,

$$E(Y) = \beta_1 x_1 + \beta_2 x_2,$$

where $x_1 = 1$ and $x_2 = 0$ for the first group, and vice versa for the second.

The estimation of the population mean from a sample is a special case, since the model is then just

$$E(Y) = \beta_0,$$

β_0 being the mean of the population.

This treatment of the comparison of different groups is somewhat artificial, although it is important to note that it falls under the regression rubric. Such comparisons are generally carried out

by means of the technique known as the analysis of variance [see LINEAR HYPOTHESES, article on ANALYSIS OF VARIANCE].

When a regressor is not measured quantitatively but is given only as a ranking (for example, order in time of archeological specimens, social position of occupation), it may still provide a regression relation suitable for estimation or prediction. The simplest way to include such a variable in a relation is to replace the qualitative values (rankings) by arbitrary numerical scores, equally spaced (see, for example, Strodbeck et al. 1957). More refined methods would use scores spaced according to some measure of "distance" between successive rankings; thus, in some instances the scores have been chosen so that their frequency distribution approximates a grouped normal distribution. Since any method of scoring is arbitrary, the method that is used must be judged by the relations based on it as well as by its theoretical cogency. Simple scoring systems, which can be easily understood, are usually to be preferred.

When both the dependent variable and the regression variable are qualitative, each may be replaced by arbitrary scores as indicated above. Alternative methods determine scores for the dependent variable that are most highly correlated (formally) with the regressor scores or, if the regressor scores for any set of data are open to choice, choose scores for both variables so that the correlation is maximized. The calculation and interpretation of the regression relations for such situations have been discussed by Yates (1948) and by Williams (1952).

Regression, correlation, functional relation. The regression relation is a one-way relation between variables in which the expected value of one random variable is related to nonrandom values of the other variables. It is to be distinguished from other types of statistical relations, in particular from correlation and functional relationships. [See MULTIVARIATE ANALYSIS, articles on CORRELATION.] Correlation is a relation between two or more random variables and may be described in terms of the amount of variation in one of the variables associated with variation in the other variable or variables. The functional relation, by contrast, is a relation between the *expected values* of random variables. If quantities related by some physical law are subject to errors of measurement, the functional relation between expected values, rather than the regression relation, is what the investigator generally wants to determine.

Although the regression relation relates a random variable to other, nonrandom variables, in

many situations it will apply also when the regression variables are random; then the regression, conditional on the observed values of the random regression variables, is determined. Here the *expected value* of one random variable is related to the *observed values* of the other random variables. For a discussion of the fitting of regression lines when the regression variables are subject to error, see Madansky (1959). When more than one variable is to be considered as random, the problem is usually thought of as one of multivariate analysis [see MULTIVARIATE ANALYSIS].

History. The method of least squares, on which most methods of estimation for linear models are based, was apparently first published by Adrien Legendre (1805), but the first treatment along the lines now familiar was given by Carl Friedrich Gauss (1821, see in 1855). Gauss showed that the method gives estimators of the unknown parameters with minimum variance among unbiased linear estimators. This basic result is sometimes known as the Gauss-Markov theorem, and the least squares estimators as Gauss-Markov estimators.

The term "regression" was first used by Francis Galton, who applied it to certain relations in the theory of heredity, but the term is now applied to relationships in general and to nonlinear as well as to linear relationships.

The linearity of linear hypotheses rests in the way the parameters appear; the x 's may be highly nonlinear functions of underlying nonrandom variables. For example,

$$\eta = \beta_0 + \beta_1 x_1 + \beta_2 x_1^2 + \beta_3 x_1^3$$

and

$$\eta = \beta_1 e^{x_1} + \beta_2 \tan x_1$$

both fall squarely under the linear hypothesis model, whereas

$$\eta = \beta_1 e^{\beta_2 x_1}$$

does not fit that model.

There is now a vast literature dealing with the linear model, and the subject is also treated in most statistical textbooks.

Application in the social sciences. There has been a good deal of discussion about the type of model that should be used to describe relations between variables in the social sciences, particularly in economics. Linear regression models have often been considered inadequate for complex economic phenomena, and more complicated models have been developed. Recent work, however, indicates that ordinary linear regression methods have a wider scope than had been supposed. For example, there has been much discussion about how

to treat data correlated in time, for which the residuals from the regression equation (the e 's) show autocorrelation. This autocorrelation may be the result of autocorrelation in the variables not included in the model. Geary (1963) suggests that in such circumstances the inclusion of additional regression variables may effectively eliminate the autocorrelation among the residuals, so that standard methods may be applied.

Further discussion of the applicability of regression methods to economic data is given by Ezekiel and Fox (1930, chapters 20 and 24) and also by Wold and Jürén (see in Wold 1953).

Investigators should be encouraged to employ the simple methods of regression analysis as a first step before turning to more elaborate techniques. Despite the relative simplicity of its ideas, it is a powerful technique for elucidating relations, and its results are easily understood and applied. More elaborate techniques, by contrast, do not always provide a readily comprehensible interpretation.

Assumptions in regression analysis. A regression model may be expressed in the following way:

$$E(Y) = \eta = \beta_0 + \beta_1 x_1 + \cdots + \beta_p x_p, \\ Y = \eta + e,$$

where Y is the random variable, η is its expected value, the x 's are known variables, the β 's are unknown coefficients, and e is a random error or deviation with zero mean. In the notation for variables, either fixed or random, subscripts are used only to distinguish the different variables but not to distinguish different observations of the same variable. The context generally makes the meaning clear. Thus, the above expression is an abbreviated form of

$$E(Y_j) = \eta_j = \beta_0 + \beta_1 x_{1j} + \beta_2 x_{2j} + \cdots + \beta_p x_{pj}, \\ Y_j = \eta_j + e_j, \\ j = 1, 2, \dots, n;$$

This model is perfectly general; however, in estimating the coefficients, it is usually assumed that the e_j are mutually uncorrelated and are of equal variance (homoscedastic).

If there is no regressor variable that is identically one (as in the two-sample situation described earlier), the β_0 term might well be omitted. This is primarily a matter of notational convention.

The additional assumption that the errors are normally distributed is convenient and simplifies the theory. It can be shown that, on this assumption, the linear estimators given by least squares are in fact the maximum likelihood (m.l.) estimators of the parameters. In addition, the residual sum of squares $\sum(Y - \hat{\eta})^2$ (see below) is the basis for the m.l. estimator of the error variance (σ^2).

Apart from the theoretical advantages of the assumption of normality of the e 's, there are the practical advantages that efficient methods of estimation and suitable tests of significance are relatively easy to apply and that the test statistics have well-known properties and are extensively tabulated. The normality assumption is often reasonable in applications, since even appreciable departures from it do not as a rule seriously invalidate regression analyses based upon normality [see ERRORS, *article on EFFECTS OF ERRORS IN STATISTICAL ASSUMPTIONS*].

Some departures from assumptions may be expected in certain situations. For example, if some of the measurements of Y are much larger than others, the associated errors, either errors of measurement or errors resulting from uncontrolled random effects, may well be correspondingly larger, so that the variances of the errors will be heterogeneous (the errors are heteroscedastic). Again, with annual data it is to be expected that errors may arise from unobserved factors whose influence from year to year will be associated, so the errors will not be independent (but see Geary 1963). It is often possible in particular cases to transform the data so that they conform more closely to the assumptions; for instance, a logarithmic or square-root transformation of Y will often give a variable whose errors have approximately constant variance [see STATISTICAL ANALYSIS, SPECIAL PROBLEMS OF, *article on TRANSFORMATIONS OF DATA*]. This will amount to replacing the linear model for Y with a linear model for the transformed variable. In practice this often gives a satisfactory representation of the data, any departure from the model being attributed to error.

The method of least squares determines, for the parameters β_i in the regression equation, estimators that minimize the sum of squares of deviations of the Y -values from the values given by the equation. This sum of squares is

$$\sum(Y - \eta)^2 = \sum(Y - \beta_0 - \beta_1 x_1 - \cdots - \beta_p x_p)^2.$$

In the following discussion the estimated β 's are denoted by b 's, and the corresponding estimator of η is denoted by $\hat{\eta}$, so that

$$\hat{\eta} = b_0 + b_1 x_1 + \cdots + b_p x_p$$

and the minimized sum of squared deviations is $\sum(Y - \hat{\eta})^2$.

The method has the twofold merit of minimizing not only the sum of squares of deviations but also the variance of the estimators b_i (among unbiased linear estimators). Thus, for most practical purposes the method of least squares gives estimators with satisfactory properties. Sometimes such esti-

meters are not appropriate—for example, when errors in one direction are more serious than those in the other—but those cases are usually apparent to the investigator.

The method of least squares applies equally well when the errors are heteroscedastic or even correlated, provided the covariance structure of the errors is known (apart from a constant of proportionality, which may be estimated from the data). The method can be generalized to take account of the general correlation structure or, equivalently, a linear transformation of the observations may be used to reduce the problem to the simpler case of uncorrelated homoscedastic errors. (Details may be found in Rao 1965, chapter 4.)

When the correlation structure is unknown, the method of least squares may still be applied. If the data are analyzed as though the errors are uncorrelated and homoscedastic, the estimators of the parameters will be unbiased, although they will be less precise than if based on the correct model.

On the other hand, if the assumed linear model is incorrect—for example, if the relation is quadratic in one of the variables but only a linear model is fitted—then the estimators are liable to serious bias.

Since the form of the underlying model is almost always unknown there is usually a corresponding risk of bias. This problem has been studied in various contexts, but there is still much to be done; see Box and Wilson (1951), Box and Andersen (1955), and Plackett (1960, chapter 2).

Simple linear regression

In the simple linear regression model the expected value of Y is a linear function of a single variable, x_1 :

$$E(Y) = \eta = \beta_0 + \beta_1 x_1.$$

The parameter β_0 is the intercept, and the parameter β_1 is the slope, of the regression line. This model is a satisfactory one in many cases, even if a number of variables affect the expected value of Y , for one of these may have a predominating influence, and although the omission of variables from the relation will lead to some bias, this may not be important in view of the increased simplicity of the model.

In studying the relation between two variables it is almost always desirable to plot a scatter diagram of the points representing the observations. The x -axis, or abscissa, is usually used for the regression variable and the y -axis, or ordinate, for the random variable. If the regression relation is linear the points should show a tendency to fall near a straight line, though if the variation is large

this tendency may well be masked. Although for some purposes a line drawn "by eye" is adequate to represent the regression, in general such a line is not sufficiently accurate. There is always the risk of bias in both the position and the slope of the line. Because there is a tendency for the deviations from the line in both the x and y directions to be taken into account in determining the fit, lines fitted by eye are often affected by the scales of measurement used for the two axes. Since Y is the random variable, only the deviations in the y direction should be taken into account in determining the fit of the line. Often the investigator, knowing that there may be error in x_1 , may attempt to take it into account. It should be understood that this procedure will give an estimate not of the regression relation but of underlying structure, which often differs from the regression relation. Another and more serious shortcoming of lines drawn by eye is that they do not provide an estimate of the variance about the line, and such an estimate is almost always required.

The method of least squares is commonly used when an arithmetical method of fitting is required, because of its useful properties and its relative ease of application. The equations for the least squares estimators, b_1 , based on n pairs of observations (x_1, Y) , are as follows:

$$b_1 = \sum Y(x_1 - \bar{x}_1) / \sum (x_1 - \bar{x}_1)^2, \\ b_0 = \bar{Y} - b_1 \bar{x}_1.$$

Here the summation is over the observed values, $\bar{x}_1 = \sum x_1 / n$, and $\bar{Y} = \sum Y / n$. (Note that the observations on x_1 need not be all different, although they must not all be the same.) The estimated regression function is

$$\hat{\eta} = b_0 + b_1 x_1.$$

The minimized sum of squares of deviations is

$$\sum (Y - \hat{\eta})^2 = \sum (Y - \bar{Y})^2 - b_1^2 \sum (x_1 - \bar{x}_1)^2 \\ - \sum (Y - \bar{Y})(x_1 - \bar{x}_1) b_1.$$

The standard errors (estimated standard deviations) of the estimators may be derived from the minimized sum of squares of deviations. Two independent linear parameters have been fitted, and it may readily be shown that the expected value of this minimized sum of squares is $(n - 2) \sigma^2$, where σ^2 is the common variance of the residual errors. Consequently, an unbiased estimator of σ^2 is given by

$$s^2 = \sum (Y - \hat{\eta})^2 / (n - 2),$$

and this is the conventional estimator of σ^2 . (The m.l. estimator of σ^2 is $\sum (Y - \hat{\eta})^2 / n$.) The sum of

squares for deviations is said to have $n - 2$ degrees of freedom, representing the number of linearly independent quantities on which it is based.

The estimated variances of the estimators are $\text{est. var } (b_1) = s^2 / \sum (x_i - \bar{x}_1)^2$ and $\text{est. var } (b_0) = s^2 \sum x_i^2 / [n \sum (x_i - \bar{x}_1)^2]$, and the estimated covariance is $\text{est. cov } (b_0, b_1) = -s^2 \bar{x}_1 / \sum (x_i - \bar{x}_1)^2 = -\bar{x}_1 \text{ var } (b_1)$.

Separate confidence limits for the parameters β_0 and β_1 may be determined from the estimators and their standard errors, using Student's t -distribution [see ESTIMATION, article on CONFIDENCE INTERVALS AND REGIONS]. If $t_{\alpha; n-2}$ denotes the α -level of this distribution for $n - 2$ degrees of freedom, the $1 - \alpha$ confidence limits for β_1 are $b_1 \pm t_{\alpha; n-2} s / \sqrt{\sum (x_i - \bar{x}_1)^2}$. Confidence limits for the intercept, β_0 , may be determined in a similar way but are not usually of interest. In a few cases it may be necessary to determine whether the estimator b_0 is in agreement with some theoretical value of the intercept. Thus, in some situations it is reasonable to expect the regression line to pass through the origin, so that $\beta_0 = 0$. It will then be necessary to test the significance of the departure of b_0 from zero or, equivalently, to determine whether the confidence limits for β_0 include zero.

When it is assumed that $\beta_0 = 0$ and there is no need to test this hypothesis, then the regression has only one unknown parameter; in such a case the sum of squares for deviations from the regression line, used to estimate the residual variance, will have $n - 1$ degrees of freedom.

When the parameters β_0 and β_1 are both of interest, a joint confidence statement about them may be useful. The joint confidence region is usually an ellipse centered at (b_0, b_1) and containing all values of (β_0, β_1) from which (b_0, b_1) does not differ with statistical significance as measured by an F -test (see the section on significance testing, below). [The question of joint confidence regions is discussed further in LINEAR HYPOTHESES, article on MULTIPLE COMPARISONS.]

Choice of experimental values. The formula for the variance of the regression coefficient b_1 shows that it is the more accurately determined the larger is $\sum (x_i - \bar{x}_1)^2$, the sum of squares of the values of x_i about their mean. This is in accordance with common sense, since a greater spread of experimental values will magnify the regression effect yet will in general leave the error component unaltered. If accurate estimation of β_1 were the only criterion, the optimum allocation of experimental points would be in equal numbers at the extreme ends of the possible range. However, the assumption that a regression is linear, although satisfactory over most of the possible range, is often likely

to fail near the ends of the range; for this and other reasons it may be desirable to check the linearity of the regression, and to do so points other than the two extreme values must be observed. In practice, where little is known about the form of the regression relation it is usually desirable to take points distributed uniformly throughout the range. If the experimental points are equally spaced, this will facilitate the fitting of quadratic or higher degree polynomials, using tabulated orthogonal polynomials as described below.

Confidence limits for the regression line. The estimated regression function is

$$\hat{\eta} = b_0 + b_1 x_1 \\ = \bar{Y} + b_1 (x_1 - \bar{x}_1),$$

and corresponding to any specified value, x_1 , of x_1 , the variance of $\hat{\eta}$ is estimated as

$$\text{est. var } (\hat{\eta}) = s^2 \left(\frac{1}{n} + \frac{(x_1 - \bar{x}_1)^2}{\sum (x_i - \bar{x}_1)^2} \right).$$

Thus, for any specified value of x_1 , confidence limits for η can be determined according to the formula

$$Y_L = \hat{\eta} \pm t_{\alpha; n-2} s \sqrt{\left(\frac{1}{n} + \frac{(x_1 - \bar{x}_1)^2}{\sum (x_i - \bar{x}_1)^2} \right)}.$$

The locus of these limits consists of the two branches of a hyperbola, lying on either side of the fitted regression line; this locus defines what may be described as a confidence curve. A typical regression line fitted to a set of points is shown in Figure 1 with the 95 per cent confidence curve shown as the two inside upper and lower curves, Y_L .

The above limits are appropriate for the estimated value of η corresponding to a given value of x_1 . They do not, however, set limits to the whole line. Such limits are given by a method developed by Working and Hotelling, as described, e.g., by Kendall and Stuart ([1943-1946] 1958-1966, vol. 2, chapter 28). [See also LINEAR HYPOTHESES, article on MULTIPLE COMPARISONS.] As might be expected, these limits lie outside the corresponding limits for the same probability for a single value of x_1 . The limits may be regarded as arising from the envelope of all lines whose parameters fall within a suitable confidence region. These limits are given by

$$Y_{WH} = \hat{\eta} \pm s \sqrt{2F_{1-\alpha; 2, n-2} \left(\frac{1}{n} + \frac{(x_1 - \bar{x}_1)^2}{\sum (x_i - \bar{x}_1)^2} \right)},$$

where $F_{1-\alpha; 2, n-2}$ is the tabulated value for the F -distribution with 2 and $n - 2$ degrees of freedom at confidence level $1 - \alpha$. These limits, for a 95 per cent confidence level, are shown as a pair of broken lines in Figure 1.

Figure 1 — Regression line and associated 95 per cent confidence regions*

* The Y_P curves, although they appear straight in the figure, are hyperbolae like the other Y curves.

Source of data: Martin, Jean I., 1965, *Refugee Settlers. A Study of Displaced Persons in Australia*. Canberra: Australian National University.

The user of the confidence limits must be clear about which type of limits he requires. If he is interested in the limits on the estimated η for a particular value x_1 , or in only one pair of limits at a time, the inner limits, Y_L , will be appropriate, but if he is interested in limits for many values of x_1 , (some of which may not be envisaged when the calculations are being made), the Working-Hotelling limits, Y_{WH} , will be needed.

Application of the regression equation. The regression equation is usually determined not only to provide an empirical law relating variables but also as a means of making future estimates or predictions. Thus, in studies of demand, regression relations of demand on price and other factors enable demand to be predicted for future occasions when one or more of these factors is varied. Such prediction is provided directly by the regression equation. It should be noted, however, that the standard error of prediction will be greater than the standard error of the estimated points ($\hat{\eta}$) on the regression line. This is because a future observation will vary about its regression value with variance equal to the variance of individual values about the regression in the population. When standard errors are being quoted, it is important to distinguish between the standard error of the point $\hat{\eta}$ on the

regression line and the standard error of prediction. The estimated variance of prediction is

$$\text{est. var } (\hat{\eta}_P) = s^2 \left(1 + \frac{1}{n} + \frac{(x_1 - \bar{x}_1)^2}{\sum (x_1 - \bar{x}_1)^2} \right).$$

The outside upper and lower curves in Figure 1 are confidence limits for prediction, Y_P , based on this variance. Clearly, for making predictions of this sort there is little point in determining the regression line with great accuracy. The major part of the error in such cases will be the variance of individual values.

The formula for the standard error of $\hat{\eta}$ or $\hat{\eta}_P$ shows that the error of estimation increases as the x_1 -value departs from the mean of the sample, so that when the deviation from the mean is large the variance of estimate can be so great as to make the estimate worthless. This is one reason why investigators should be discouraged from attempting to draw inferences beyond the range of the observed values of x_1 . The other reason is that the assumed linear regression, even though satisfactory within the observed range, may not hold true outside this range.

Inverse estimation. In many situations the investigator is primarily interested in determining the value of x_1 corresponding to a given level or value, η . Thus, although it is still appropriate to determine the regression of the random variable Y on the fixed variable x_1 , the inference has to be carried out in reverse. For example, if a drug that affects the reaction time of individuals is being tested at different levels, the reaction time Y will be a random variable with regression on the dose level x_1 . However, the purpose of the investigation may be to determine a dose level that will lead to a given time of reaction on the average. The experimental doses, being fixed, cannot be treated as random, so that it is inappropriate to determine a regression of x_1 on Y , and such a pseudo regression would give spurious results. In such situations the value of x_1 corresponding to a given value of η has to be estimated from the regression of Y on x_1 .

The regression equation can be rearranged to give an estimator of x_1 corresponding to a given value, η .

$$\hat{X}_1 = (\eta - b_0)/b_1.$$

The approximate estimated variance of the estimator is

$$\begin{aligned} \text{est. var } (\hat{X}_1) &\approx \frac{s^2}{b_1^2} \left(\frac{1}{n} + \frac{(\hat{X}_1 - \bar{x}_1)^2}{\sum (x_1 - \bar{x}_1)^2} \right) \\ &= \frac{s^2}{b_1^2} \left(\frac{1}{n} + \frac{(\eta - \bar{Y})^2}{\sum (x_1 - \bar{x}_1)^2} \right). \end{aligned}$$

A more precise method of treating such a problem is to determine confidence limits for η given x_1 and

to determine from these, by rearranging the equation, confidence limits for x_1 . For the regression shown in Figure 1, the 95 per cent confidence curves (the inner curves, Y_L , on either side of the line) will in this way give confidence limits for x_1 corresponding to a given value of η . The point at which the horizontal line $Y = \eta$ cuts the regression line gives the estimate of x_1 ; the points at which the line cuts the upper and lower curves give, respectively, lower and upper confidence limits for x_1 . This may be demonstrated by an extension of the reasoning leading to confidence limits. [See ESTIMATION, article on CONFIDENCE INTERVALS AND REGIONS.]

Sometimes, rather than a hypothetical regression value, η_* , a single observed value, y_* (not in the basic sample), is given, and limits are required for the value of x_1 that could be associated with such a value. The estimator \hat{X}_* is given by

$$\hat{X}_* = (y_* - b_0)/b_1,$$

and its approximate estimated variance (which must take into account the variation between responses on Y to a given value of x_1) is

$$\text{est. var } (\hat{X}_*) = \frac{s^2}{b_1^2} \left(1 + \frac{1}{n} + \frac{(\hat{X}_* - \bar{x})^2}{\sum (x_i - \bar{x})^2} \right).$$

Using this augmented variance, confidence limits on x_1 corresponding to a given y_* may be found. For more precise determination of the confidence limits for prediction, the locus of limits for y_* given x_1 may be inverted to give limits for x_1 given y_* . In Figure 1, the outer curves are these loci (for the 95 per cent confidence level); the 95 per cent limits for x_1 will be given by the intersection of the line $Y = y_*$ with these confidence curves for prediction.

Multiple regression

In many situations where a single regression variable is not adequate to represent the variation in the random variable Y , a multiple regression is appropriate. In other situations there may be only one regression variable, but the assumed relation, rather than being linear, is a quadratic or a polynomial of higher degree. Since both multiple linear regression and polynomial regression relations are linear in the unknown parameters, the same techniques are applicable to both; in fact, polynomial regression is a special case of multiple regression. The number of variables to include in a multiple regression, or the degree of polynomial to be applied, is to some extent a matter of judgment and convenience, although it must be remembered that a regression equation containing

a large number of variables is usually inconvenient to use as well as difficult to calculate. With the use of electronic computers, however, there is greater scope for increasing the number of regression variables, since the computations are routine.

Consider the multiple regression equation

$$E(Y) = \eta = \beta_0 + \beta_1 x_1 + \cdots + \beta_p x_p,$$

with p regression variables and a constant term. The estimation of these $p + 1$ unknown parameters can be systematically carried out if β_0 is also regarded as a regression coefficient corresponding to a regression variable x_0 that is always unity. As in simple regression, the method of least squares provides unbiased linear estimators of the coefficients with minimum variance and also provides estimators of the standard errors of these coefficients. The quantities required for determining the estimators are the sums of squares and products of the x -values, the sums of products of the observed Y with each of the x -values, and the sum of squares of Y . The method of least squares gives a set of linear equations for the b 's, called the *normal equations*:

$$\begin{aligned} b_0 t_{00} + b_1 t_{01} + \cdots + b_p t_{0p} &= u_0 \\ b_0 t_{10} + b_1 t_{11} + \cdots + b_p t_{1p} &= u_1 \\ &\vdots \\ b_0 t_{p0} + b_1 t_{p1} + \cdots + b_p t_{pp} &= u_p \end{aligned}$$

where $t_{hi} = t_{ih} = \sum x_i x_h$ and $u_i = \sum Y x_i$. These equations can be written in matrix form as

$$\mathbf{Tb} = \mathbf{u},$$

where $\mathbf{T} = (t_{hi})$ and \mathbf{u} is the vector of the u_i . The solution requires the inversion of the matrix \mathbf{T} , the inverse matrix being denoted by \mathbf{T}^{-1} (with typical element t^{hi}). The solution may be written in matrix form as

$$\mathbf{b} = \mathbf{T}^{-1}\mathbf{u}$$

or in extended form as

$$b_0 = t^{00}u_0 + t^{01}u_1 + \cdots + t^{0p}u_p,$$

and so forth.

The variance of b_i is $t^{ii}\sigma^2$, and the covariance of b_i and b_j is $t^{ij}\sigma^2$. It should be remarked that in the special case of "regression through the origin"—that is, when the constant term β_0 is assumed to be zero—the first equation and the first term of each other equation are omitted; the constant regressor x_0 and its coefficient β_0 thus have the same status as any other regression variable.

When the constant term is included, computational labor may be reduced and arithmetical accuracy increased if the sums of squares and

products are taken about the means. That is, the t_{hi} and u_i are replaced by

$$t'_{hi} = t_{hi} - \sum x_h \sum x_i / n = \sum (x_h - \bar{x}_h)(x_i - \bar{x}_i)$$

and

$$u'_i = u_i - \sum Y \sum x_i / n,$$

respectively. All the sums of products with zero subscripts then vanish, and the sums of squares are reduced in magnitude. The constant term has to be estimated separately; it is given by

$$\begin{aligned} b_0 &= \bar{Y} - b_1 \bar{x}_1 - b_2 \bar{x}_2 - \cdots - b_p \bar{x}_p \\ &= (\sum Y - b_1 \sum x_1 - b_2 \sum x_2 - \cdots - b_p \sum x_p) / n. \end{aligned}$$

The computational aspects of matrix inversion and the determination of the regression coefficients are dealt with in many statistical texts, including Williams (1959); in addition, many programs for matrix inversion are available for electronic computers.

Effect of heteroscedasticity. When the error variance of the dependent variable Y is different in different parts of its range (or, strictly, of the range of its expected value, η), estimators of regression coefficients ignoring the heteroscedasticity will be unbiased but of reduced accuracy, as already mentioned. The calculation of improved estimators may then sometimes be necessary.

There are some problems in taking heteroscedasticity into account. Among them is the problem of specification: defining the relation between expected value and variance. Often, with adequate data, the estimated ($\hat{\eta}$) values from the usual unweighted regression line can be grouped and the mean squared deviation from these values for each group used as a rough measure of the variance. The regression can then be refitted, each value being given a weight inversely proportional to the estimated variance. Two iterations of this method are likely to give estimates of about the accuracy practically attainable. If an empirical relation between expected value and error variance can be deduced, this simplifies the problem somewhat; however, the weight for each observation has to be determined from a provisionally fitted relation, so iteration is still required.

To calculate a weighted regression, each observation Y_j ($j = 1, 2, \dots, n$) is given a weight w_j instead of unit weight as in the standard calculation. These weights will be the reciprocals of the estimated variances of each value. Then, if weighted quantities are distinguished by the subscript w ,

$$\begin{aligned} t_{whi} &= \sum w x_{hi} x_i, \\ u_{wi} &= \sum w Y x_i, \end{aligned}$$

and the normal equations are

$$b_{w0} t_{w00} + b_{w1} t_{w01} + \cdots + b_{wp} t_{w0p} = u_{w0}$$

and so on, or in matrix form

$$\mathbf{T}_w \mathbf{b}_w = \mathbf{u}_w.$$

The solution is

$$\mathbf{b}_w = \mathbf{T}_w^{-1} \mathbf{u}_w,$$

and the variances of the estimators b_{wi} are approximately $t_{wi}^{-1} \sigma^2$.

When the weights are estimated from the data, as in the iterative method just described, some allowance has to be made in an exact analysis for errors in the weights. This inaccuracy will somewhat reduce the precision of the estimators. However, for most practical purposes, and provided that the number of observations in each group for which weights are estimated is not too small, the errors in the weights may be ignored. (For further discussion of this question see Cochran & Carroll 1953.)

Estimability of the coefficients. It is intuitively clear in a general way that the $p+1$ regression variables included in a regression equation should not be too nearly linearly dependent on one another, for then it might be expected that these regression variables could be approximately expressed in terms of a smaller number.

More precisely, in order that meaningful estimators of the regression coefficients exist, it is necessary that the variables be linearly independent (or, equivalently, \mathbf{T} must be nonsingular). That is, no one variable should be expressible as a linear combination of the others or, expressed symmetrically, no linear combination of the variables vanishes unless all coefficients are zero. Clearly, if only $p-r$ of the variables are linearly independent, then the regression relation may be represented as a regression on these $p-r$, together with arbitrary multiples of the vanishing linear combinations. From the practical point of view, this lack of estimability will cause no problems, provided that the regression on a set of $p-r$ linearly independent variables is calculated. Estimation from the equation will be unaffected, but for testing the significance of the regression it must be noted that the regression sum of squares has not $p+1$ but $p-r$ degrees of freedom, and the residual has $n-p+r$.

However, if the lack of estimability is ignored, the calculations to determine the $p+1$ coefficients either will fail (since the matrix \mathbf{T} , being singular, has no inverse) or will give misleading results (if an approximate value of \mathbf{T} , having an inverse, is

used in calculation and the lack of estimability is obscured).

When the regression variables, although linearly independent, are barely so (in the sense that the matrix T , although of rank $p + 1$, is "almost singular," having a small but nonvanishing determinant), the regression coefficients will be estimable but will have large standard errors. In typical cases, many of the estimated coefficients will not differ with statistical significance from zero; this merely reflects the fact that the corresponding regression variable may be omitted from the equation and the remaining coefficients adjusted without significant worsening of the fit.

In this situation, as in the case of linear dependence, these effects are not usually important in practice; however, they may suggest the advisability of reducing the number of regression variables included in the equation. [For further discussion, see STATISTICAL IDENTIFIABILITY.]

Conditions on the coefficients. Sometimes the regression coefficients β_i are assumed to satisfy some conditions based on theory. Provided these conditions are expressible as linear equations in the coefficients, the method of least squares carries through and leads, as before, to unbiased estimators satisfying the conditions and with minimum variance among linear estimators. It will be clear that with $p + 1$ regression coefficients subject to $r + 1$ independent linear restrictions, $r + 1$ of the coefficients may be eliminated, so that the restricted regression is equivalent to one with $p - r$ coefficients. Thus, in principle there is a choice between expressing the model in terms of $p - r$ unrestricted coefficients or $p + 1$ restricted ones; often the latter has advantages of symmetry and interpretability.

A simple example of restricted regression is one in which η is a weighted average of the x 's but with unknown weights, β_1, \dots, β_p . Here the side conditions would be $\beta_0 = 0$, $\beta_1 + \dots + \beta_p = 1$.

As the introduction of side conditions effectively reduces the number of linearly independent coefficients, such conditions are useful in restoring estimability when the coefficients are nonestimable. In many problems these side conditions may be chosen to have practical significance. For example, where an over-all mean and a number of treatment "effects" are being estimated, it is conventional to specify the effects so that their mean vanishes; with this specification they represent deviations from the over-all mean.

When a restricted regression is being estimated, it will often be possible and of interest to estimate the unrestricted regression as well, in order to see

the effect of the restrictions and to test whether the data are concordant with the conditions assumed. The test of significance consists of comparing the $(p + 1)$ -variable (unrestricted) regression with the $(p - r)$ -variable (restricted) regression, in the manner described in the section on significance testing. This test of concordance is independent of the test of significance of any of the restricted coefficients.

Further details and examples of restricted regression are given by Rao (1965, p. 189) and Williams (1959, pp. 49–58). In the remainder of this article, the notation will presume unrestricted regression.

Missing values. When observations on some of the variables are missing, the simplest and usually the only practicable procedure is to ignore the corresponding values of the other variables—that is, to work only with complete sets of observations. However, it is sometimes possible to make use of the incomplete data, provided some additional assumptions are made. Methods have been developed under the assumption that (a) the missing values are in some sense randomly deleted, or the assumption that (b) the variables are all random and follow a multivariate normal distribution. Assumption (b) is treated by Anderson (1957) and Rao (1952, pp. 161–165). It is sometimes found, after the least squares equations for the constants in a regression relation have been set up, that some of the values of the dependent variable are unreliable or missing altogether. Rather than recalculate the equations it is often more convenient to replace the missing value by the value expected from the regression relation. This substitution conserves the form of the estimating equations, usually with little disturbance to the significance tests or the variances of the estimators.

The techniques of "fitting missing values" have been most fully developed for experiments designed in such a way that the estimators of various constants are either uncorrelated or have a symmetric pattern of correlations and the estimating equations have a symmetry of form that simplifies their solution. Missing values in such experiments destroy the symmetry and make estimation more difficult; it is therefore a great practical convenience to replace the missing values. Details of the method applied to designed experiments will be found in Cochran and Cox (1950). For applications to general regression models see Kruskal (1961).

The technique is itself an application of the method of least squares. To replace a missing value Y_j , a value $\hat{\eta}_j$ is chosen so as to minimize its contribution to the residual sum of squares. Thus, the

estimate is equivalent to the one that would have been obtained by a fresh analysis; the calculation is simplified by the fact that estimates for only one or a few values are being calculated. The degrees of freedom for the residual sum of squares are reduced by the number of values thus fitted. For most practical purposes it is then sufficiently accurate to treat the fitted values as though they were original observations. The exact analysis is described by Yates (1933) and, in general terms, by Kruskal (1961).

Significance testing. In order to determine the standard errors of the regression coefficients and to test their significance, it is necessary to estimate the residual variance, σ^2 . The sum of squares of deviations, $\sum(Y - \hat{\eta})^2$, which may readily be shown to satisfy

$$\begin{aligned}\sum(Y - \hat{\eta})^2 &= \sum Y^2 - \mathbf{u}'\mathbf{T}^{-1}\mathbf{u} \\ &= \sum Y^2 - \mathbf{b}'\mathbf{u},\end{aligned}$$

is found under $p + 1$ constraints and so may be said to have $n - p - 1$ degrees of freedom; if the model assumed is correct, so that the deviations are purely random, the expected value of the sum of squares is $(n - p - 1)\sigma^2$. Accordingly, the *residual mean square*,

$$s^2 = \sum(Y - \hat{\eta})^2 / (n - p - 1),$$

is an unbiased estimator of the residual variance. The variances of the regression coefficients are estimated by

$$\text{est. var}(b_i) = t^{ii}s^2,$$

and the standard errors are the square roots of these quantities. The inverse matrix thus is used both in the calculation of the estimators and in the determination of their standard errors. From the off-diagonal elements t^{ij} of the inverse matrix are derived the estimated covariances between the estimators,

$$\text{est. cov}(b_i, b_j) = t^{ij}s^2.$$

The splitting of the total sum of squares of Y into two parts, a part associated with the regression effects and a residual part independent of

them, is a particular example of what is known as the analysis of variance [see LINEAR HYPOTHESES, *article on ANALYSIS OF VARIANCE*].

Testing for regression effects. The regression sum of squares, being based on $p + 1$ estimated quantities, will have $p + 1$ degrees of freedom. When regression effects are nonexistent, the expected value of each part is proportional to its degrees of freedom. Accordingly, it is often convenient and informative to present these two parts, and their corresponding mean squares, in an analysis-of-variance table, such as Table 1.

In the table, the final column gives the expected values of the two mean squares; it shows that real regression effects inflate the regression sum of squares but not the residual sum of squares. This fact provides the basis for tests of significance of a calculated regression, since large values of the ratio of regression mean square to residual mean square give evidence for the existence of a regression relation.

Significance of a single coefficient. The question may arise whether one or more of the regression variables contribute to the relation anything that is not already provided by the other variables. In such circumstances the relevant hypothesis to be examined is that the β 's corresponding to these variables are zero. A more general hypothesis that may sometimes need to be tested is that certain of the β 's take assigned values.

The simplest test is that of the statistical significance of a single coefficient—say, b_i . The test will be of its departure from zero, if the contribution of x_i to the regression is in question. More generally, when β_i is specified, as, say, β_i^* , it will be relevant to test the significance of departure of b_i from β_i^* . The significance test in either case is the same; the squared difference between estimated and hypothesized values is compared with the estimated variance of that difference, which is $s^2 t^{ii}$.

The ratio $F = (b_i - \beta_i^*)^2 / (s^2 t^{ii})$ has the F -distribution with 1 and $n - p - 1$ degrees of freedom if the difference is in fact due to sampling fluctuations alone; in this case, the F -statistic is just the square of the usual t -statistic. When β_i differs

Table 1 — Analysis-of-variance table for testing regression effects

Source	Degrees of freedom	Sum of squares	Mean square	Expected mean square
Regression	$p + 1$	$\sum b_i u_i$	$\frac{\sum b_i u_i}{p + 1}$	$\sigma^2 + \frac{\mathbf{b}'\mathbf{T}\mathbf{b}}{p + 1}$
Residual	$n - p - 1$	$\sum Y^2 - \sum b_i u_i = (n - p - 1)s^2$	s^2	σ^2
Total	n	$\sum Y^2$		

from β_1^* the F -statistic will tend to be larger, so that a right-tail test is indicated.

Testing several coefficients. To test a number of regression variables—or, more precisely, their regression coefficients—the method of least squares is equivalent to fitting a regression with and without the variables in question and testing the difference in the regression sums of squares against the estimated error variance. To choose a specific example, suppose the last q coefficients in a p -variable regression are to be tested. If the symbol S^2 is used to stand for sum of squares, the sum of squares for regression on all p variables may be written

$$S_p^2 = \mathbf{u}'_p \mathbf{T}_p^{-1} \mathbf{u}_p,$$

with $p + 1$ degrees of freedom, and the corresponding sum of squares on the first $p - q$ variables as

$$S_{p-q}^2 = \mathbf{u}'_{p-q} \mathbf{T}_{p-q}^{-1} \mathbf{u}_{p-q}$$

with $p - q + 1$ degrees of freedom. The difference, a sum of squares with q degrees of freedom, provides a criterion for testing the significance of the q regression coefficients. The ratio

$$F = (S_p^2 - S_{p-q}^2) / (qs^2)$$

has, under the null hypothesis that the last q coefficients are zero, the F -distribution with q and $n - p - 1$ degrees of freedom. This simultaneous test of q coefficients may also be adapted to testing the departure of the q coefficients from theoretical values, not necessarily zero.

The significance test may be conveniently set out as in Table 2, where only the mean squares required for the significance test appear in the last column.

When $q = 1$, this test reduces to the test for a single regression coefficient, and the F -ratio

$$F = (S_p^2 - S_{p-1}^2) / s^2$$

is then identical with the F -ratio given above for making such a test.

Linear combinations of coefficients. Sometimes it is necessary to test the significance of one or more linear combinations of the coefficients—that is, to test hypotheses about linear combinations of the β 's. A common example is the comparison of two coefficients, β_1 and β_2 , say, for which the comparison $b_1 - b_2$ is relevant. The F -test applies to such comparisons also. Thus, for the difference $b_1 - b_2$, the estimated variance is $s^2(t^{11} - 2t^{12} + t^{22})$, and $F = (b_1 - b_2)^2 / [s^2(t^{11} - 2t^{12} + t^{22})]$, with 1 and $n - p - 1$ degrees of freedom.

In general, to test the departure from zero of k linear combinations of regression coefficients the procedure is as follows. Let the linear combinations (expressed in matrix notation) be

$$\Gamma' \mathbf{b},$$

where Γ is a $(p + 1) \times k$ matrix of known constants. Then the estimated covariance matrix of these linear combinations is

$$s^2 \Gamma' \mathbf{T}^{-1} \Gamma,$$

and the F -ratio is

$$F = \mathbf{b}' \Gamma (\Gamma' \mathbf{T}^{-1} \Gamma)^{-1} \Gamma' \mathbf{b} / ks^2,$$

with k and $n - p - 1$ degrees of freedom. Of course, this test can also be adapted to testing the departure of these linear combinations from pre-assigned values other than zero.

When the population coefficients β_i are in fact nonzero, the expected value of the regression mean square in the analysis of variance shown in Table 1 will be larger than σ^2 by a term that depends on both the magnitude of the coefficients and the accuracy with which they are estimated (see, for example, the last column of Table 1). Clearly, the greater this term, called the *noncentrality*, the greater the probability that the null hypothesis will be rejected at the adopted significance level. The F -test has certain optimum properties, but other tests may be preferred in special circumstances.

Table 2 — Analysis-of-variance table for testing several regression coefficients

Source	Degrees of freedom	Sum of squares	Mean square
Regression on $p - q$ variables	$p - q + 1$	S_{p-q}^2	...
Additional q variables	q	$S_p^2 - S_{p-q}^2$	$(S_p^2 - S_{p-q}^2) / q$
Regression on all p variables	$p + 1$	S_p^2	...
Residual	$n - p - 1$	$(n - p - 1)s^2$	s^2
Total	n	$\sum Y^2$	

Multivariate analogues

Although hitherto only the regression of a single dependent variable Y on one or more regressors x_i has been discussed, it will be realized that often the simultaneous regressions of a number of random variables on the same regressors will be of importance. For instance, in a sociological study of immigrants the regressions of annual income and size of family on age, educational level, and period of residence in the country may be determined: here there are two dependent variables and three regressors.

Often the relations among the different dependent variables will also be of interest, or various linear combinations of the variables, rather than the original variables themselves, may be studied. The linear combination that is most highly correlated with the regressors may sometimes be relevant to the investigation, but the linear compounds will usually be chosen for their practical relevance rather than their statistical properties. [For further discussion of multivariate analogues, see MULTIVARIATE ANALYSIS, especially the general article, OVERVIEW, and the article on CLASSIFICATION AND DISCRIMINATION.]

Polynomial regression

When the relation between two variables, x_i and Y , appears to be curvilinear, it is natural to fit some form of smooth curve to the data. For some purposes a freehand curve is adequate to represent the relation, but if the curve is to be used for prediction or estimation and standard errors are required, some mathematical method of fitting, such as the method of least squares, must be used. The freehand fitting of a curvilinear relation has all the disadvantages of freehand fitting of a straight line, with the added disadvantage that it is more difficult to distinguish real trends from random fluctuations.

The polynomial form is

$$E(Y) = \eta = \beta_0 + \beta_1 x_i + \beta_2 x_i^2 + \cdots + \beta_p x_i^p.$$

Being a linear model, it has the advantages of simplicity, flexibility, and relative ease of calculation. It is for such reasons, not because it necessarily represents the theoretical form of the relation, that a polynomial regression is often fitted to data.

Orthogonal polynomials. The computations in polynomial regression are exactly the same as those in multiple regression, except that some simplification of the arithmetic may be introduced if the same values of x_i are used repeatedly. Then instead

of using the powers of x_i as the regression variables, these are replaced by orthogonal polynomials of successively increasing degree, so defined that the sum of products of any pair of them, over their chosen values, is zero.

This procedure has the twofold advantage that, first, all the off-diagonal elements of the matrix \mathbf{T} are zero, so the calculation of regression coefficients and their standard errors is much simplified, and, second, the regression coefficient on each polynomial and the corresponding sum of squares can be independently determined.

Because it is common for investigators to use data with values of the independent variables equally spaced, the orthogonal polynomials for this particular case have been extensively tabulated. Fisher and Yates (1938) tabulate these orthogonal polynomials up to those of fifth degree, for numbers of equally spaced points up to 75. However, if the data are not equally spaced the tabulated polynomials are not applicable, and the regression must be calculated directly.

Testing adequacy of fit. The question of what degree of polynomial is appropriate to fit to a set of data is discussed below (see "Considerations in regression model choice"). If for each value of x_i there is an array of values for Y , the variation in the data can be analyzed into parts between and within arrays by the techniques of analysis of variance [see LINEAR HYPOTHESES, article on ANALYSIS OF VARIANCE]. The sum of squares between arrays can be further analyzed into that part accounted for by regression and that part not so accounted for (deviation from regression). The adequacy of a polynomial fitted to the data is indicated by non-significant deviation from regression.

When there is but one observation of Y for each value of x_i , such an analysis is not possible. To test the adequacy of a p th-degree polynomial regression, a common though not strictly defensible procedure is to fit a polynomial of degree $p + 1$ and test whether the coefficient b_{p+1} of x_i^{p+1} is significant. Anderson (1962) has treated this problem as a multiple decision problem and has provided optimal procedures that can readily be applied.

Estimation of maxima. Sometimes a polynomial regression is fitted in order to estimate the value of x_i that yields a maximum value of η . A detailed discussion of the estimation of maxima is given by Hotelling (1941). To give an idea of the methods that are used, consider a quadratic regression of the form

$$\eta = b_0 + b_1 x_i + b_2 x_i^2.$$

A maximum (or minimum) value of $\hat{\eta}$ occurs at the point $x_m = -b_1/2b_2$, and this value is taken as the estimated position of the maximum. Confidence limits for the position can be determined by means of the following device. If the position of the maximum of the true regression curve is ξ , then $\xi = -\beta_1/2\beta_2$, so that $\beta_1 + 2\beta_2\xi = 0$. Consequently the quantity

$$b_1 + 2b_2\xi$$

is distributed with mean zero and estimated variance

$$s^2(t^{11} + 4t^{12}\xi + 4t^{22}\xi^2).$$

The confidence limits for ξ with confidence coefficient $1 - \alpha$ are given by the roots of the equation

$$\frac{(b_1 + 2b_2\xi)^2}{s^2(t^{11} + 4t^{12}\xi + 4t^{22}\xi^2)} = F_{\alpha; 1, n-3},$$

where $F_{\alpha; 1, n-3}$ is the α -point of the F -distribution with 1 and $n - 3$ degrees of freedom, abbreviated below as F_α . The solution of this equation may be simplified by writing

$$g_{11} = \frac{F_\alpha s^2 t^{11}}{b_1^2}, \quad g_{12} = \frac{F_\alpha s^2 t^{12}}{b_1 b_2}, \quad g_{22} = \frac{F_\alpha s^2 t^{22}}{b_2^2},$$

so that the confidence limits become

$$X_L = x_m \frac{(1 - g_{12}) \pm \sqrt{(1 - g_{12})^2 - (1 - g_{11})(1 - g_{22})}}{1 - g_{22}}.$$

Note that these limits are not, in general, symmetrically placed about the estimated value $-b_1/2b_2$, since allowance is made for the skewness of the distribution of the ratio. Note also that the limits will include infinite values and will therefore not be of practical use, unless b_2 is significant at the α -level. In terms of the g -values, this means that g_{22} must not exceed 1.

When the regression model is a polynomial in two or more variables, investigation of maxima and other aspects of shape becomes more complex. [A discussion of this problem appears in EXPERIMENTAL DESIGN, article on RESPONSE SURFACES.]

Nonlinear models

In a nonlinear model the regression function is nonlinear in one or more of the parameters. Familiar examples are the exponential regression,

$$\eta = \beta_0 + \beta_1 e^{\beta_2 x_1},$$

and the logistic curve,

$$\eta = \frac{\beta_1}{1 + e^{-\beta_2 x_1}},$$

β_2 being the nonlinear parameter in each example. Such nonlinear models usually originate from theo-

retical considerations but nevertheless are often useful for applying to observational data.

Sometimes the model can be reduced to a linear form by a transformation of variables (and a corresponding change in the specification of the errors). The exponential regression with $\beta_0 = 0$ may thus be reduced by taking logarithms of the dependent variable and assuming that the errors of the logarithms, rather than the errors of the original values, are distributed about zero. If $Z = \log_e Y$ and $E(Z) = \xi$, the exponential model with $\beta_0 = 0$ reduces to $\xi = \log_e \beta_1 + \beta_2 x_1$, a linear model.

The general models shown above cannot be reduced to linear models in this way. For nonlinear models generally, the nonlinear parameters must be estimated by successive approximation. The following method is straightforward and of general applicability.

Suppose the model is

$$\eta = \beta_0 + \beta_1 f(x_1, \beta_2)$$

where $f(x_1, \beta_2)$ is a nonlinear function of β_2 , and the estimated regression, determined by least squares, is

$$\hat{\eta} = b_0 + b_1 f(x_1, c).$$

If c_0 is a trial value of c (estimated by graphical or other means), the values of $f(x_1, c)$ and its first derivative with respect to c (denoted, for brevity, by f and f' , respectively) are calculated for each value of x_1 , with $c = c_0$. The regression of Y on f and f' is then determined in the usual way, yielding the regression equation

$$\hat{\eta} = b_0 + b_1 f + b_2 f'.$$

A first adjustment to c_0 is given by b_2/b_1 , giving the new approximation

$$c_1 = c_0 + b_2/b_1.$$

The process of recalculating the regression on f and f' and determining successive approximations to c can be continued until the required accuracy is attained (for further details see Williams 1959).

The method is an adaptation of the *delta method*, which utilizes the principle of *propagation of error*. If a small change, $\delta\beta_2$, is made in a parameter β_2 , the corresponding change in a function $f(\beta_2)$ is, to a first approximation, $f'(\beta_2)\delta\beta_2$. The use of this method allows the replacement of the nonlinear equations for the parameters by approximate linear equations for the adjustments. For a regression relation of the form

$$\eta = \beta_0 + \beta_1 e^{\beta_2 x_1},$$

Stevens (1951) provides a table to facilitate the calculation of the nonlinear parameter by a method

similar to that described above, and Pimentel Gomes (1953) provides tables from which, with a few preliminary calculations, the least squares estimate of the nonlinear parameter can be read off easily.

Considerations in regression model choice

In deciding which of several alternative models shall be used to interpret a relationship, a number of factors must be taken into account. Other things being equal, the model which represents the predictands most closely (where "closeness" is measured in terms of some criterion such as minimum mean square error among linear estimators) will be used. However, questions of convenience and simplicity should also be considered. A regression equation that includes a large number of regression variables is not convenient to use, and an equation with fewer variables may be only slightly less accurate. In deciding between alternative models, the residual variance is therefore not the only factor to take into account.

In polynomial regression particularly, the assumed polynomial form of the model is usually chosen for convenience, so that a polynomial of given degree is not assumed to be the true regression model. Because of this, the testing of individual polynomial coefficients is little more than a guide in deciding on the degree of polynomial to be fitted. Of far more importance is a decision on what degree of variability about the regression model is acceptable, and this decision will be based on practical rather than merely statistical considerations.

Besides the question of including additional variables in a regression, for which significance tests have already been described, there is also the question of alternative regression variables. The alternatives for a regression relation could be different variables or different functions of the same variable—for instance, x_1 and $\log x_1$.

For comparison of two or more individual variables as predictors, a test devised by Hotelling (1940) is suitable, although not strictly accurate. It is based on the correlations between Y and the different predictors and of the predictors among themselves. For comparing two regression variables x_1 and x_2 , the test statistic is

$$F = \frac{(u'_1/\sqrt{t'_{11}} - u'_2/\sqrt{t'_{22}})^2}{2s^2(1 - t'_{12}/\sqrt{t'_{11}t'_{22}})},$$

which is distributed approximately as F with 1 and $n - 3$ degrees of freedom. Here, as before,

$$u'_i = \sum Y(x_i - \bar{x}_i),$$

$$t'_{hi} = \sum (x_h - \bar{x}_h)(x_i - \bar{x}_i),$$

and s^2 is the mean square of residuals from the regression of Y on x_1 and x_2 , with $n - 3$ degrees of freedom.

ANALYSIS OF VARIANCE

Analysis of variance is a body of statistical procedures for analyzing observational data that may be regarded as satisfying certain broad assumptions about the structure of means, variances, and distributional form. The basic notion of analysis of variance (or ANOVA) is that of comparing and dissecting empirical dispersions in the data in order to understand underlying central values and dispersions.

This basic notion was early noted and developed in special cases by Lexis and von Bortkiewicz [see LEXIS; BORTKIEWICZ]. Not until the pioneering work of R. A. Fisher (1925; 1935), however, were the fundamental principles of analysis of variance and its most important techniques worked out and made public [see FISHER, R. A.]. Early applications of analysis of variance were primarily in agriculture and biology. The methodology is now used in every field of science and is one of the most important statistical areas for the social sciences. (For further historical material see Sampford 1964.)

Much basic material of analysis of variance may usefully be regarded as a special development

of regression analysis [see LINEAR HYPOTHESES, article on REGRESSION]. Analysis of variance extends, however, to techniques and models that do not strictly fall under the regression rubric.

In analysis of variance all the standard general theories of statistics, such as point and set estimation and hypothesis testing, come into play. In the past there has sometimes been overemphasis on testing hypotheses.

One-factor analysis of variance

A simple experiment will now be described as an example of ANOVA. Suppose that the publisher of a junior-high-school textbook is considering styles of printing type for a new edition, there are three styles to investigate, and the same chapter of the book has been prepared in each of the three styles for the experiment. Junior-high-school pupils are to be chosen at random from an appropriate large population of such pupils, randomly assigned to read the chapter in one of the three styles, and then given a test that results in a reading-comprehension score for each pupil.

Suppose that the experiment is set up so that P_1 , P_2 , and P_3 pupils (where $P_1 = P_2 = P_3 = P$) read the chapter in styles 1, 2, and 3, respectively, and that X_{ps} denotes the comprehension score of the p th pupil reading style s . (Here $s = 1, 2, 3$; in general, $s = 1, 2, \dots, S$.) There is a hypothetical mean, or expected, value of X_{ps} , μ_s , but X_{ps} differs from μ_s because, first, the pupils are chosen randomly from a population of pupils with different inherent means and, second, a given pupil, on hypothetical repetitions of the experiment, would not always obtain the same score. This is expressed by writing

$$(1) \quad X_{ps} = \mu_s + e_{ps}.$$

Then the assumptions are made that the e_{ps} are all independent, that they are all normally distributed, and that they have a common (usually unknown) variance, σ^2 . By definition, the expectation of e_{ps} is zero.

Because differences among the pupils reading a particular style of type are thrown into the random "error" terms (e_{ps}), the expectation of X_{ps} , does not depend on p . It is convenient to rewrite (1) as

$$X_{ps} = \mu + (\mu_s - \mu) + e_{ps},$$

where $\mu = (\sum \mu_s)/S$, the average of the μ_s . For simplicity, set $\alpha_s = \mu_s - \mu$ (so that $\alpha_1 + \alpha_2 + \dots + \alpha_S = 0$) and write the structural equation finally in the conventional form

$$(2) \quad X_{ps} = \mu + \alpha_s + e_{ps}.$$

Here α_s is the differential effect on comprehension scores of style s for the relevant population of pupils. The unknowns are μ , the α_s , and σ^2 .

Note that this structure falls under the linear regression hypothesis with coefficients 0 or 1. For example, if $E(X_{ps})$ represents the expected value of X_{ps} ,

$$E(X_{p1}) = 1 \cdot \mu + 1 \cdot \alpha_1 + 0 \cdot \alpha_2 + 0 \cdot \alpha_3 + \dots + 0 \cdot \alpha_s,$$

$$E(X_{p2}) = 1 \cdot \mu + 0 \cdot \alpha_1 + 1 \cdot \alpha_2 + 0 \cdot \alpha_3 + \dots + 0 \cdot \alpha_s.$$

Consider how this illustrative experiment might be conducted. After defining the population to which he wishes to generalize his findings, the experimenter would use a table of random numbers to choose pupils to read the chapter printed in the different styles. (Actually, he would probably have to sample intact school classes rather than individual pupils, so the observations analyzed might be class means instead of individual scores, but this does not change the analysis in principle.) After the three groups have read the same chapter under conditions that differ only in style of type, a single test covering comprehension of the material in the chapter would be administered to all pupils.

The experimenter's attention would be focused on differences between average scores of the three style groups (that is, $\bar{X}_{.1}$ versus $\bar{X}_{.2}$, $\bar{X}_{.2}$ versus $\bar{X}_{.3}$, and $\bar{X}_{.1}$ versus $\bar{X}_{.3}$) relative to the variability of the test scores within these groups. He estimates the μ_s via the $\bar{X}_{.s}$, and he attempts to determine which of the three averages, if any, differ with statistical significance from the others. Eventually he hopes to help the publisher decide which style of type to use for his new edition.

ANOVA of random numbers—an example. An imaginary experiment of the kind outlined above will be analyzed here to illustrate how ANOVA is applied. Suppose that the three P_s are each 20, that in fact the μ_s are all exactly equal to 0, and that $\sigma^2 = 1$ (setting $\mu_s = 0$ is just a convenience corresponding to a conventional origin for the comprehension-score scale).

Sixty random normal deviates, with mean 0 and variance 1, were chosen by use of an appropriate table (RAND Corporation 1955). They are listed in Table 1, where the second column from the left should be disregarded for the moment—it will be used later, in a modified example. From the "data" of Table 1 the usual estimates of the μ_s are just the column averages, $\bar{X}_{.1} = -0.09$, $\bar{X}_{.2} = 0.10$, and $\bar{X}_{.3} = 0.08$. The estimate of μ is the over-all mean, $\bar{X}_{..} = 0.03$, and the estimates of the α_s are $-0.09 - 0.03 = -0.12$, $0.10 - 0.03 = 0.07$, and $0.08 - 0.03 = 0.05$. Note that these add to zero,

* This column was obtained by adding 1 to each deviate of the first column.

as required. In ANOVA, for this case, two quantities are compared. The first is the dispersion of the three μ_s estimates—that is, the sum of the $(\bar{X}_{.s} - \bar{X}_{..})^2$, conveniently multiplied by 20, the common sample size. This is called the between-styles dispersion or sum of squares. Here it is 0.4466. (These calculations, as well as those below, are made with the raw data of Table 1, not with the rounded means appearing there.) The second quantity is the within-sample dispersion, the sum of the three quantities $\sum_p (X_{ps} - \bar{X}_{.s})^2$. This is called the within-style dispersion or sum of squares. Here it is 50.1253.

This comparison corresponds to the decomposition

$$X_{ps} - \bar{X}_{..} = (\bar{X}_{.s} - \bar{X}_{..}) + (X_{ps} - \bar{X}_{.s})$$

and to the sum-of-squares identity

$$\begin{aligned} \sum_p \sum_s (X_{ps} - \bar{X}_{..})^2 &= \sum_p \sum_s (\bar{X}_{.s} - \bar{X}_{..})^2 + \sum_p \sum_s (X_{ps} - \bar{X}_{.s})^2 \\ &= 20 \sum_s (\bar{X}_{.s} - \bar{X}_{..})^2 + \sum_p \sum_s (X_{ps} - \bar{X}_{.s})^2, \end{aligned}$$

which shows how the factor of 20 arises. Such identities in sums of squares are basic in most elementary expositions of ANOVA.

The fundamental notion is that the within-style dispersion, divided by its so-called *degrees of freedom* (here, degrees of freedom for error), unbiasedly estimates σ^2 . Here the degrees of freedom for error are 57 (equals 60 [for the total number of

Table 2 — Analysis-of-variance table for one-factor experiment

(a) ANOVA of 60 random normal deviates

Source of variation	df	SS	MS	F	Tabled $F_{.05;2,57}$
Between styles	3 - 1 = 2	0.4466	0.2233	0.25	3.16
Within styles	60 - 3 = 57	50.1253	0.8794*		
Total	60 - 1 = 59	50.5719			

* Actually, σ^2 here is known to be 1.(b) ANOVA of general one-factor experiment with S treatments

Source of variation	df	MS	EMS
Between treatments	$S - 1$	$\sum_{s=1}^S P_s (\bar{X}_{..} - \bar{X}_{..})^2 / (S - 1)$	$\sigma^2 + \sum_{s=1}^S P_s \alpha_s^2 / (S - 1)$
Within treatments	$P_s - S^*$	$\sum_{s=1}^S \sum_{p=1}^{P_s} (X_{sp} - \bar{X}_{..})^2 / (P_s - S)^*$	σ^2
Total	$P_s - 1^*$	$\sum_{s=1}^S \sum_{p=1}^{P_s} (X_{sp} - \bar{X}_{..})^2 / (P_s - 1)^*$	

* Here P_s is used for $\sum_{p=1}^{P_s} P_p$ for convenience.

observations] minus 3 [for the number of μ_s estimated]). On the other hand, the between-styles dispersion, divided by its degrees of freedom (here 2), estimates σ^2 unbiasedly if and only if the μ_s are equal; otherwise the estimate will tend to be larger than σ^2 . Furthermore, the between-styles and within-style dispersions are statistically independent. Hence, it is natural to look at the ratio of the two dispersions, each divided by its degrees of freedom. The result is the F -statistic, here

$$\frac{0.4466/2}{50.1253/57} = 0.25.$$

In repeated trials with the null hypothesis (that there are no differences between the μ_s) true, the F -statistic follows an F -distribution with (in this case) 2 and 57 degrees of freedom (see DISTRIBUTIONS, STATISTICAL, article on SPECIAL CONTINUOUS DISTRIBUTIONS). Level of significance is denoted by " α " (which should not be confused with the totally unrelated " α_s ," denoting style effect; the notational similarity stems from the juxtaposition of two terminological traditions and the finite number of Greek letters). The F -test at level of significance α of the null hypothesis that the styles are equivalent rejects that hypothesis when the F -statistic is too large, greater than its 100α percentage point, here $F_{.05;2,57}$. If $\alpha = 0.05$, which is a conventional level, then $F_{.05;2,57} = 3.16$, so 0.25 is much smaller than the cutoff point, and the null hypothesis is, of course, not rejected. This is consonant with the fact that the null hypothesis is true in the imaginary experiment under discussion.

Table 2 summarizes the above discussion in both algebraic and numerical form. The algebraic form is for S styles with P_s students at the s th style.

To reiterate, in an analysis of variance each kind of effect (treatment, factor, and others to be discussed later) is represented by two basic numbers. The first is the so-called *sum of squares* (SS), corresponding to the effect; it is random, depending upon the particular sample, and has two fundamental properties: (a) If the effect in question is wholly *absent*, its sum of squares behaves probabilistically like a sum of squared independent normal deviates with zero means. (b) If the effect in question is *present*, its sum of squares tends to be relatively large; in fact, it behaves probabilistically like a sum of squared independent normal deviates with *not* all means zero.

The second number is the so-called *degrees of freedom* (df). This quantity is not random but depends only on the structure of the experimental design. The df is the number of independent normal deviates in the description of sums of squares just given.

A third (derived) number is the so-called *mean square* (MS), which is computed by dividing the sum of squares by the degrees of freedom. When an effect is wholly absent, its mean square is an unbiased estimator of underlying variance, σ^2 . When an effect is present, its mean square has an expectation greater than σ^2 .

In the example considered here, each observation is regarded as the sum of (a) a grand mean, (b) a printing-style effect, and (c) error. It is con-

ventional in analysis-of-variance tables not to have a line corresponding to the grand mean and to work with sample residuals centered on it; that convention is followed here. Printing-style effect and error differ in that the latter is assumed to be wholly random, whereas the former is not random but may be zero. The mean square for error estimates underlying variance unbiasedly and is a yardstick for judging other mean squares.

In the standard simple designs to which ANOVA is applied, it is customary to define effects so that the several sums of squares are statistically independent, from which additivity both of sums of squares and of degrees of freedom follows [see PROBABILITY, article on FORMAL PROBABILITY]. In the example, $SS_{\text{between}} + SS_{\text{within}} = SS_{\text{total}}$, and $df_b + df_w = df_{\text{total}}$. (Here, and often below, the subscripts "b" and "w" are used to stand for "between" and "within," respectively.) This additivity is computationally useful, either to save arithmetic or to verify it.

Analysis-of-variance tables, which, like Table 2, are convenient and compact summaries of both the relevant formulas and the computed numbers, usually also show *expected mean squares* (EMS), the average value of the mean squares over a (conceptually) infinite number of experiments. In fixed-effects models (such as the model of the example) these are always of the form σ^2 (the underlying variance) plus an additional term that is zero when the relevant effect is absent and positive when it is present. The additional term is a convenient measure of the magnitude of the effect.

Expected mean squares, such as those given by the two formulas in Table 2, provide a necessary condition for the F -statistic to have an F -distribution when the null hypothesis is true. (Other conditions, such as independence, must also be met.) Note that if the population mean of the s th treatment, μ_s , is the same for all treatments (that is, if $\alpha_s = 0$ for all s) then the expected value of MS_b will be σ^2 , the same as the expected value of MS_w . If the null hypothesis is true, the average value of the F from a huge number of identical experiments employing fresh, randomly sampled experimental units will be $(P - S)/(P - S - 2)$, which is very nearly 1 when, as is usually the case, the total number of experimental units, P , is large compared with S . Expected mean squares become particularly important in analyses based on models of a nature somewhat different from the one illustrated in Tables 1 and 2, because in those cases it is not always easy to determine which mean square should be used as the denominator of F (see the discussion of some of these other models, below).

The simplest t -tests. It is worth digressing to show how the familiar one-sample and two-sample t -tests (or Student tests) fall under the analysis-of-variance rubric, at least for the symmetrical two-tail versions of these tests.

Single-sample t -test. In the single-sample t -test context, one considers a random sample, X_1, X_2, \dots, X_P , of independent normal observations with the same unknown mean, μ , and the same unknown variance, σ^2 . Another way of expressing this is to write

$$X_p = \mu + e_p, \quad p = 1, \dots, P,$$

where the e_p are independent normal random variables, with mean 0 and common variance σ^2 . The usual estimator of μ is \bar{X} , the average of the X_p , and this suggests the decomposition into average and deviation from average,

$$X_p = \bar{X} + (X_p - \bar{X}),$$

from which one obtains the sum-of-squares identity

$$\begin{aligned} \sum X_p^2 &= \sum (X_p - \bar{X})^2 + \sum \bar{X}^2 + 2\bar{X} \cdot \sum (X_p - \bar{X}) \\ &= \sum (X_p - \bar{X})^2 + P\bar{X}^2 \end{aligned}$$

(since $\sum (X_p - \bar{X}) = 0$), a familiar algebraic relationship. Since the usual unbiased estimator of σ^2 is $s^2 = \sum (X_p - \bar{X})^2 / (P - 1)$, the sum-of-squares identity may be written

$$\sum X_p^2 = (P - 1)s^2 + P\bar{X}^2.$$

Ordinarily the analysis-of-variance table is not written out for this simple case; it is, however, the one shown in Table 3. In Table 3 the total row is the actual total including all observations; it is of the essence that the row for mean is separated out.

Table 3

Effect	df	SS	EMS
Mean	1	$P\bar{X}^2$	$\sigma^2 + P\mu^2$
Error	$P - 1$	$\sum (X_p - \bar{X})^2$	σ^2
Total	P	$\sum X_p^2$	

The F -statistic for testing that $\mu = 0$ is the ratio of the mean squares for mean and error,

$$\frac{P\bar{X}^2}{\sum (X_p - \bar{X})^2 / (P - 1)} = \frac{P\bar{X}^2}{s^2},$$

which, under the null hypothesis, has an F -distribution with 1 and $P - 1$ degrees of freedom. Notice that the above F -statistic is the square of

$$\frac{\bar{X}}{s/\sqrt{P}},$$

which is the ordinary t -statistic (or Student statistic) for testing $\mu = 0$. If a symmetrical two-tail test is wanted, it is immaterial whether one deals with the t -statistic or its square. On the other hand, for a one-tail test the t -statistic would be referred to the t -distribution with $P - 1$ degrees of freedom [see DISTRIBUTIONS, STATISTICAL, article on SPECIAL CONTINUOUS DISTRIBUTIONS].

It is important to note that a confidence interval for μ may readily be established from the above discussion [see ESTIMATION, article on CONFIDENCE INTERVALS AND REGIONS]. The symmetrical form is

$$\bar{X} - \sqrt{F_{\alpha/2, P-1}} s / \sqrt{P} \leq \mu \leq \bar{X} + \sqrt{F_{\alpha/2, P-1}} s / \sqrt{P}.$$

Alternatively, $F_{\alpha/2, P-1}$ can be replaced by the upper $100(\alpha/2)$ per cent point for the t -distribution with $P - 1$ degrees of freedom, $t_{\alpha/2, P-1}$.

Suppose, for example, that from a normally distributed population there has been drawn a random sample of 25 observations for which the sample mean, \bar{x} , is 34.213 and the sample variance, s^2 , is 49.000. What is the population mean, μ ? The usual point estimate from this sample is 34.213. How different from μ is this value likely to be? For $\alpha = .05$, a 95 per cent confidence interval is constructed by looking up $t_{.025, 24} = 2.064$ in a table (for instance, McNemar [1949] 1962, p. 430) and substituting in the formula

$$\text{Confidence} \left[34.213 - 2.064 \left(\frac{\sqrt{49.000}}{\sqrt{25}} \right) \leq \mu \leq 34.213 + 2.064 \left(\frac{\sqrt{49.000}}{\sqrt{25}} \right) \right] = 0.95.$$

Thus,

$$\text{Confidence} [31.32 \leq \mu \leq 37.10] = 0.95.$$

This result means that if an infinite number of samples, each of size $P = 25$, were drawn randomly from a normally distributed population and a confidence interval for each sample were set up in the above way, only 5 per cent of the intervals would fail to cover the mean of the population (which is a certain fixed value).

Similarly, from this one sample the unbiased point estimate of σ^2 is the value of s^2 , 49.000. Brownlee ([1960] 1965, page 282) shows how to find confidence intervals for σ^2 [see also VARIANCES, STATISTICAL STUDY OF].

Is it "reasonable" to suppose that the mean of the population from which this sample was randomly chosen is as large as, say, 40? No, because that number does not lie within even the 99 per cent confidence interval. Therefore it would be

unreasonable to conclude that the sample was drawn from a population with a mean as great as 40. The relevant test of statistical significance is

$$t = \frac{34.213 - 40.000}{7/5} = \frac{-5.787(5)}{7} = -4.134,$$

the absolute magnitude of which lies beyond the 0.9995 percentile point (3.745) in the tabled t -distribution for 24 degrees of freedom. Therefore, the difference is statistically significant beyond the $0.0005 + 0.0005 = 0.001$ level. The null hypothesis being tested was $H_0: \mu = 40$, against the alternative hypothesis $H_a: \mu \neq 40$. Just as the confidence interval indicated that it is unreasonable to suppose the mean to be equal to 40, this test also shows that 40 will lie outside the 99 per cent confidence interval; however, of the two procedures, the confidence interval gives more information than the significance test.

Two-sample t -test. In the two-sample t -test context, there are two random samples from normal distributions assumed to have the same variance, σ^2 , and to have means μ_1 and μ_2 . Call the observations in the first sample X_{11}, \dots, X_{P_1} , and the observations in the second sample X_{12}, \dots, X_{P_2} . The most usual null hypothesis is $\mu_1 = \mu_2$, and for that the t -statistic is

$$\frac{\bar{X}_{..} - \bar{X}_{..}}{s \sqrt{(1/P_1) + (1/P_2)}},$$

where the P 's are the sample sizes, the \bar{X} 's are the sample means, and s^2 is the estimate of σ^2 based on the pooled within-sample sum of squares,

$$s^2 =$$

$$\frac{1}{P_1 + P_2 - 2} \left\{ \sum_p (X_{p1} - \bar{X}_{..})^2 + \sum_p (X_{p2} - \bar{X}_{..})^2 \right\}.$$

Here $P_1 + P_2 - 2$ is the number of degrees of freedom for error, the total number of observations less the number of estimated means ($\bar{X}_{..}$ and $\bar{X}_{..}$ estimate μ_1 and μ_2 , respectively). Under the null hypothesis, the t -statistic has the t -distribution with $P_1 + P_2 - 2$ degrees of freedom.

The basic decomposition is

$$X_{ps} - \bar{X}_{..} = (\bar{X}_{.s} - \bar{X}_{..}) + (X_{ps} - \bar{X}_{.s}),$$

leading to the sum-of-squares decomposition

$$\begin{aligned} \sum_p \sum_s (X_{ps} - \bar{X}_{..})^2 \\ = \sum_s P_s (\bar{X}_{.s} - \bar{X}_{..})^2 + \sum_p \sum_s (X_{ps} - \bar{X}_{.s})^2. \end{aligned}$$

Since s has only the values 1 and 2,

$$\bar{X}_{..} = \frac{P_1}{P_1 + P_2} \bar{X}_{.1} + \frac{P_2}{P_1 + P_2} \bar{X}_{.2},$$

Table 4

Effect	df	SS	EMS*
Style	1	$\sum P_i(\bar{X}_{.i} - \bar{X}_{..})^2 = \frac{(\bar{X}_{.1} - \bar{X}_{.2})^2}{(1/P_1) + (1/P_2)}$	$\sigma^2 + \frac{(\mu_1 - \mu_2)^2}{(1/P_1) + (1/P_2)}$
Error	$P_1 + P_2 - 2$	$(P_1 + P_2 - 2)s^2$	σ^2
Total	$P_1 + P_2 - 1$	$\sum \sum (X_{pi} - \bar{X}_{..})^2$	

* Note that the expected mean square for style is σ^2 plus what is obtained by formal substitution for the random variables $(\bar{X}_{.1}, \bar{X}_{.2})$ in the sum of squares of their respective expectations (divided by df, which here is 1). This relationship is a perfectly general one in the analysis-of-variance model now under discussion, but it must be changed for other models that will be mentioned later.

and therefore

$$\begin{aligned} \sum P_i(\bar{X}_{.i} - \bar{X}_{..})^2 &= \frac{P_1 P_2}{P_1 + P_2} (\bar{X}_{.1} - \bar{X}_{.2})^2 \\ &= \frac{(\bar{X}_{.1} - \bar{X}_{.2})^2}{(P_1 + P_2)/P_1 P_2} \\ &= \frac{(\bar{X}_{.1} - \bar{X}_{.2})^2}{(1/P_1) + (1/P_2)}. \end{aligned}$$

The analysis-of-variance table may be written as in Table 4. The F -statistic for the null hypothesis that $\mu_1 = \mu_2$ is

$$\frac{(\bar{X}_{.1} - \bar{X}_{.2})^2 / (P_1^{-1} + P_2^{-1})}{s^2} = \frac{(\bar{X}_{.1} - \bar{X}_{.2})^2}{s^2[(1/P_1) + (1/P_2)]},$$

and this is exactly the square of the t -statistic for the two-sample problem.

Note that the two-sample problem as it is analyzed here is only a special case (with $S = 2$) of the S -sample problem presented earlier.

The numerical example continued. Returning to the numerical example of Table 1, add 1 to every number in the leftmost column to obtain the second column and consider the numbers in the second column as the observations for style 1. Now $\mu_1 = 1$ and $\mu_2 = \mu_3 = 0$. What happens to the analysis of variance and the F -test? Table 5 shows the result; the F -statistic is 5.41, which is of high statistical significance since $F_{0.01, 2, 57} = 5.07$. Thus, one would correctly reject the null hypothesis of equality among the three μ 's.

The actual value of μ is $\frac{1}{3} \cong 0.33$, and that of α_1 is $\frac{2}{3} \cong 0.67$. The estimate of μ is 0.36, and that of α_1 is 0.55.

With three styles, one can consider many contrasts—for example, style 1 versus style 2, style 1

versus style 3, style 2 versus style 3, $\frac{1}{2}$ (style 1 + style 2) versus style 3. There are special methods for dealing with several contrasts simultaneously [see LINEAR HYPOTHESES, article on MULTIPLE COMPARISONS].

ANOVA with more than one factor

In the illustrative example being considered here, suppose that the publisher had been interested not only in style of type but also in a second factor, such as the tint of the printing ink (t). If he had three styles and four tints, a complete "crossed" factorial design would require $3 \times 4 = 12$ experimental conditions ($s_1 t_1, s_1 t_2, \dots, s_3 t_4$). From 12P experimental units he would assign P units at random to each of the 12 conditions, conduct his experiment, and obtain outcome measures to analyze. The total variation between the 12P outcome measures can be partitioned into four sources rather than into the two found with one factor. The sources of variation are the following: between styles, between tints, interaction of styles with tints, and within style-tint combinations (error).

The usual model for the two-factor crossed design is

$$X_{pst} = \mu + \alpha_s + \beta_t + \gamma_{st} + e_{pst},$$

where $\sum_s \alpha_s = \sum_t \beta_t = \sum_s \gamma_{st} = \sum_t \gamma_{st} = 0$, and the e_{pst} are independent normally distributed random variables with mean 0 and equal variance σ^2 for each st combination. The analysis-of-variance procedure for this design appears in Table 6. The α_s and β_t represent main effects of the styles and tints; the γ_{st} denote (two-factor) interactions.

Table 5 — One-factor ANOVA of 60 transformed random normal deviates

Source of variation	df	SS	MS	EMS	F
Between styles	2	8.9246	4.4623	$\sigma^2 + 20 \sum_{s=1}^3 \alpha_s^2 / 2$	5.41
Within styles	57	50.1253	0.8794	σ^2	
Total	59	59.0499			

Table 6 — ANOVA of a complete, crossed-classification, two-factor factorial design with P experimental units for each factor-level combination

Source of variation	df	SS	EMS
Between styles	$S - 1$	$PT \sum_{s=1}^S (\bar{X}_{..s} - \bar{X}_{...})^2$	$\sigma^2 + PT \sum_s \alpha_s^2 / (S - 1)$
Between tints	$T - 1$	$PS \sum_{t=1}^T (\bar{X}_{...t} - \bar{X}_{...})^2$	$\sigma^2 + PS \sum_t \beta_t^2 / (T - 1)$
Styles \times tints (interaction)	$(S - 1)(T - 1)$	$P \sum_{s=1}^S \sum_{t=1}^T (\bar{X}_{.st} - \bar{X}_{.s.} - \bar{X}_{...t} + \bar{X}_{...})^2$	$\sigma^2 + P \sum_s \sum_t \gamma_{st}^2 / (S - 1)(T - 1)$
Within style-tint combinations	$ST(P - 1)$	$\sum_{s=1}^S \sum_{t=1}^T \sum_{p=1}^P (X_{pst} - \bar{X}_{.st})^2$	σ^2
Total	$PST - 1$	$\sum_{s=1}^S \sum_{t=1}^T \sum_{p=1}^P (X_{pst} - \bar{X}_{...})^2$	

Interaction. The two-factor design introduces interaction, a concept not relevant in one-factor experiments. It might be found, for example, that, although in general s_1 is an ineffective style and t_1 is an ineffective tint, the particular combination $s_1 t_1$ produces rather good results. It is then said that style interacts with tint to produce nonadditive effects; if the effects were additive, an ineffective style combined with an ineffective tint would produce an ineffective combination.

Interaction is zero if $E(X_{pst}) = \mu + \alpha_s + \beta_t$ for every st , because under this condition the population mean of the st th combination is the population grand mean plus the sum of the effects of the s th style and the t th tint. Then the interaction effect, γ_{st} , is zero for every combination. Table 7 contains hypothetical data showing population means, $\bar{\mu}_{st}$, for zero interaction (Lubin 1961 discusses types of interaction). Note that for every cell of Table 7, $\bar{\mu}_{st} - (\bar{\mu}_{.s.} - \mu) - (\bar{\mu}_{...t} - \mu) = \mu = 3$. (Here $\bar{\mu}_{...}$ is written as μ for simplicity.) For example, for tint 1 and style 1, $3 - (5 - 3) - (1 - 3) = 3$.

One tests for interaction by computing $F_{MS_{\text{styles} \times \text{tints}} / MS_{\text{within style-tint}}}$, comparing this F with the F 's tabulated at various significance levels for $(S - 1)(T - 1)$ and $ST(P - 1)$ degrees of freedom.

Table 7 — Zero interaction of two factors (hypothetical population means $\bar{\mu}_{st}$)

Style \ Tint	Tint				Row means ($\bar{\mu}_{.s.}$)
	1	2	3	4	
1	3	4	5	8	5
2	0	1	2	5	2
3	0	1	2	5	2
Column means ($\bar{\mu}_{...t}$)	1	2	3	6	$3 = \mu$

If there were but one subject reading with each style-tint combination (that is, if there were no replication), further assumptions would have to be made to permit testing of hypotheses about main effects. In particular, it is commonly then assumed that the style \times tint interaction is zero, so that the expected mean square for interaction in Table 6 reduces to the underlying variance, and the $MS_{\text{styles} \times \text{tints}}$ may be used in the denominator of the F 's for testing main effects. No test of the assumption of additivity is possible through $MS_{\text{within style-tint}}$, because this quantity cannot be calculated. However, Tukey (1949; see also Winer 1962, pp. 216-220) has provided a one-degree-of-freedom test for interaction, or nonadditivity, of a special kind that can be used for testing the hypothesis of no interaction for these unreplicated experiments of the fixed-effects kind. (See Scheffé 1959, pp. 129-134.)

The factorial design may be extended to three or more factors. With three factors there are four sums of squares for interactions: one for the three-factor interaction (sometimes called a second-order interaction, because a one-factor "interaction" is a main effect) and one each for the three two-factor (that is, first-order) interactions. If the three factors are A , B , and C , their interactions might be represented as $A \times B \times C$, $A \times B$, $A \times C$, and $B \times C$. For example, a style of type that for the experiment as a whole yields excellent comprehension may, when combined with a generally effective size of type and a tint of paper that has over-all facilitative effect, yield rather poor results. One three-factor factorial experiment permits testing of the hypothesis that there is a no second-order interaction and permits the magnitude of such interaction to be estimated, whereas three one-factor experiments or a two-factor experiment and a one-factor experiment do not. Usually, three-

factor nonadditivity is difficult to explain substantively.

A large number of more complex designs, most of them more or less incomplete in some respect as compared with factorial designs of the kind discussed above, have been proposed. [See EXPERIMENTAL DESIGN; see also Winer 1962; Fisher 1935.]

The analysis of covariance

Suppose that the publisher in the earlier, style-of-type example had known reading-test scores for his 60 pupils prior to the experiment. He could have used these antecedent scores in the analysis of the comprehension scores to reduce the magnitude of the mean square within styles, which, as the estimate of underlying variance, is the denominator of the computed F . At the same time he would adjust the subsequent style means to account for initial differences between reading-test-score means in the three groups. One way of carrying out this more refined analysis would be to perform an analysis of variance of the differences between final comprehension scores and initial reading scores—say, $X_{ps} - Y_{ps}$. A better prediction of the outcome measure, X_{ps} , might be secured by computing $\alpha + \beta Y_{ps}$, where α and β are constants to be estimated.

By a statistical procedure called the *analysis of covariance* one or more antecedent variables may be used to reduce the magnitude of the sum of squares within styles and also to adjust the observed style means for differences between groups in average initial reading scores. If $\beta \neq 0$, then the adjusted sum of squares within treatments (which provides the denominator of the F -ratio) will be less than the unadjusted SS_w of Table 2, thereby tending to increase the magnitude of F . For each independent antecedent variable one uses, one degree of freedom is lost for SS_w and none for SS_b ; the loss of degrees of freedom for SS_w will usually be more than compensated for by the decrease in its magnitude.

A principal statistical condition needed for the usual analysis of covariance is that the regression of outcome scores on antecedent scores is the same for every style, because one computes a single within-style regression coefficient to use in adjusting the within-style sum of squares. Homogeneity of regression can be tested statistically; see Winer (1962, chapter 11). Some procedures to adopt in the case of heterogeneity of regression are given in Brownlee (1960).

The regression model chosen must be appropriate for the data if the use of one or more antecedent variables is to reduce MS_w appreciably.

Usually the regression of outcome measures on antecedent measures is assumed to be linear.

The analysis of covariance can be extended to more than one antecedent variable and to more complex designs. (For further details see Cochran 1957; Smith 1957; Winer 1962; McNemar 1949.)

Models—fixed, finite, random, and mixed

In the example, the publisher's "target population" of styles of print consisted of just those 3 styles that he tried out, so he exhausted the population of styles of interest to him. Suppose that, instead, he had been considering 39 different styles and had drawn at random from these 39 the 3 styles he used in the experiment. His intention is to determine from the experiment based on these 3 styles whether it would make any difference which one of the 39 styles he used for the textbook (of course, in practice a larger sample of styles would be drawn). If the styles did seem to differ in effectiveness, he would estimate from his experimental data involving only 3 styles the variance of the 39 population means of the styles. Then he might perform further experiments to find the most effective styles.

Finite-effects models. Thus far in this article the model assumed has been the *fixed-effects* model, in which one uses in the experiment itself all the styles of type to which one wishes to generalize. The 3-out-of-39 experiment mentioned above illustrates a *finite-effects* model, with only a small percentage (8 per cent, in the example given) of the styles drawn at random for the experiment but where one has the intention of testing the null hypothesis

$$H_0: \mu_1 = \mu_2 = \dots = \mu_{39}$$

against all alternative hypotheses and estimating the "variance," $\sigma_{\text{style}}^2 = \sum_{s=1}^{39} (\mu_s - \mu)^2 / (39 - 1)$ from $MS_b = 20 \sum_{s=1}^3 (\bar{X}_{.s} - \bar{X}_{..})^2 / (3 - 1)$ and $MS_w = \sum_{s=1}^3 \sum_{p=1}^{20} (X_{ps} - \bar{X}_{.s})^2 / [3(20 - 1)]$.

Random-effects models. If the number of "levels" of the factor is very large, so that the number of levels drawn randomly for the experiment is a negligible percentage of the total number, then one has a *random-effects* model, sometimes called a *components-of-variance* model or *Model II*. This model would apply if, for example, one drew 20 raters at random from an actual or hypothetical population of 100,000 raters and used those 20 to rate each of 25 subjects who had been chosen at random from a population of half a million. (Strictly speaking, the number of raters and the number of subjects in the respective populations would have to be infinite to produce the

random-effects model, but for practical purposes 100,000/20 and 500,000/25 are sufficiently large.) If every rater rated every subject on one trait (say, gregariousness) there would be $20 \times 25 = 500$ ratings, one for each experimental combination—that is, one for each rater–subject combination.

This, then, would be a two-factor design without replication, that is, with just one rating per rater–subject combination. (Even if the experimenter had used available raters and subjects rather than drawing them randomly from any populations, he would probably want to generalize to other raters and subjects “like” them; see Cornfield & Tukey 1956, p. 913.)

The usual model for an experiment thus conceptualized is

$$X_{rs} = \mu + a_r + b_s + e_{rs},$$

where μ is a grand mean, the a 's are the (random) rater effects, the b 's are (random) subject effects, and the e 's combine interaction and inherent measurement error. The $20 + 25 + (20 \times 25)$ random variables are supposed to be independent and assumed to have variances as follows:

$$\text{var } a_r = \sigma_a^2, \quad \text{var } b_s = \sigma_b^2, \quad \text{var } e_{rs} = \sigma_e^2.$$

For F -testing purposes, a , b , and e are supposed to be normally distributed.

The analysis-of-variance table in such a case is similar to those presented earlier, except that the expected mean square column is changed to the one shown in Table 8.

Table 8

Effect	EMS
Rater	$\sigma_e^2 + 25 \sigma_a^2$
Subject	$\sigma_e^2 + 20 \sigma_b^2$
Error	σ_e^2

The F -statistic for testing the hypothesis that the main effect of subjects is absent (that $\sigma_b^2 = 0$) is MS_s / MS_{error} , where

$$MS_{\text{error}} = \frac{1}{19 \times 24} \sum \sum (X_{rs} - \bar{X}_{r.} - \bar{X}_{.s} + \bar{X}_{..})^2.$$

Under the null hypothesis that $\sigma_b^2 = 0$, the F -statistic has an F -distribution with 24 and 19×24 degrees of freedom. (A similar F -statistic is used for testing $\sigma_a^2 = 0$.) An unbiased estimator of σ_e^2 is

$$\frac{1}{20} (MS_s - MS_{\text{error}})$$

with a similar estimator for σ_a^2 . A serious difficulty with these estimators is that they may take negative values; perhaps the best resolution of that

difficulty is to enlarge the model. See Nelder (1954), and for another approach and a bibliography, see Thompson (1962).

Note that here it appears impossible to separate random interaction from inherent variability, both of which contribute to σ_e^2 , the variance of the e 's; in the random-effects model, however, this does not jeopardize significance tests for main effects.

In more complex Model II situations the F -tests used are inherently different from their Model I analogues; in particular, sample components of variance are often most reasonably compared, not with the “bottom” estimator of σ^2 , but with some other—usually an interaction—component of variance. (See Hays 1963, pp. 356–489; Brownlee [1960] 1965, pp. 309–396, 467–529.)

Mixed models. If all the levels of one factor are used in an experiment while a random sample of the levels of another factor is used, a *mixed model* results. Mixed models present special problems of analysis that have been discussed by Scheffé (1959, pp. 261–290) and by Mood and Graybill (1963).

Other topics in ANOVA

Robustness of ANOVA. Fixed-effects models are better understood than the other models and therefore, *where appropriate*, can be used with considerable confidence. Fixed-effects ANOVA seems “robust” for type I errors to departures from certain mathematical assumptions underlying the F -test, provided that the number of experimental units is the same for each experimental combination. Two of these assumptions are that the e 's are normally distributed and that they have common variance σ^2 for every one of the experimental combinations. In particular, the common-variance assumption can be relaxed without greatly affecting the probability values for computed F 's. If the number of experimental units does not vary from one factor-level combination to another, then it may be unnecessary to test for heterogeneity of variances preliminary to performing an ANOVA, because ANOVA is robust to such heterogeneity. (In fact, it may be unwise to make such a test, because the usual test for heterogeneity of variance is more sensitive to nonnormality than is ANOVA.) For further discussion of this point see Lindquist (1953, pp. 78–86), Winer (1962, pp. 239–241), Brownlee ([1960] 1965, chapter 9), and Glass (1966). Brownlee (1960) and others have provided the finite-model expected mean squares for the complete three-factor factorial design, from which one can readily determine expected mean

squares for three-factor fixed, mixed, and random models.

Analysis-of-variance F 's are unaffected by linear transformation of the observations—that is, by changes in the X_{ps} of the form $a + bX_{ps}$, where a and b are constants ($b \neq 0$). Multiplying every observation by b multiplies every mean square by b^2 . Adding a to every observation does not change the mean squares. Thus, if observations are two-decimal numbers running from, say, -1.22 upward, one could, to simplify calculations, drop the decimal (multiply each number by 100) and then add 122 to each observation. The lowest observation would become $100(-1.22) + 122 = 0$. Each mean square would become $100^2 = 10,000$ times as large as for the decimal fractions. With the increasing availability of high-speed digital computers, coding of data is becoming less important than it was formerly.

A brief classification of factors. The ANOVA "factors" considered thus far are style of printing type, tint of ink, rater, and subject. Styles differ from each other qualitatively, as do raters and subjects. Tint of ink might vary more quantitatively than do styles, raters, and subjects—as would, for example, size of printing type or temperature in a classroom. Thus, one basis for classifying factors is whether or not their levels are ordered and, if they are, whether meaningful numbers can be associated with the factor levels.

Another basis for classification is whether the variable is manipulated by the experimenter. In order to conduct a "true" experiment, one must assign his experimental units in some (simple or restrictive) random fashion to the levels of at least one manipulated factor. ANOVA may be applied to other types of data, such as the scores of Englishmen versus Americans on a certain test, but this is an associational study, not a stimulus-response experiment. Obviously, nationality is not an independent variable in the same sense that printing type is. The direct "causal" inference possible from a well-conducted style-of-type experiment differs from the associational information obtained from the comparison of Englishmen's scores with those of Americans (see Stanley 1961; 1965; 1966; Campbell & Stanley 1963). Some variables, such as national origin, are impossible to manipulate in meaningful ways, whereas others, such as "enrolls for Latin versus does not enroll for Latin," can in principle be manipulated, even though they usually are not.

Experimenters use nonmanipulated, classification variables for two chief reasons. First, they may wish to use a factor explicitly in a design in order

to isolate the sum of squares for the main effect of that factor so that it will not inflate the estimate of underlying variance—that is, so it will not make the denominator mean square of F unnecessarily large. For example, if the experimental units available for experimentation are children in grades seven, eight, and nine, and if IQ scores are available, it is wise in studying the three styles of type to use the three (ordered) grades as one fixed-effects factor and a number of ordered IQ levels—say, four—as another fixed-effects factor. If the experimenter suspects that girls and boys may react differently to the styles, he will probably use this two-level, unordered classification (girls versus boys) as the third factor. This would produce $3 \times 4 \times 2 \times 3 = 72$ experimental combinations, so with at least 2 children per combination he needs not less than 144 children.

Probably most children in the higher grades read better, regardless of style, than do most children in the lower grades, and children with high IQ's tend to read better than children with lower IQ's, so the main effects of grade and of IQ should be large. Therefore, the variation within grade-IQ-sex-style groups should be considerably less than within styles alone.

A second reason for using such stratifying or leveling variables is to study their interactions with the manipulated variable. Ninth graders might do relatively better with one style of type and seventh graders relatively better with another style, for example. If so, the experimenter might decide to recommend one style of type for ninth graders and another for seventh graders. With the above design one can isolate and examine one four-factor interaction, four three-factor interactions, six two-factor interactions, and four main effects, a total of $2^4 - 1 = 15$ sources of variation across conditions. In the fixed-effects model all of these are tested against the variation within the experimental combinations, pooled from all combinations. Testing 15 sources of variation instead of 1 will tend to cause more apparently significant F 's at a given tabled significance level than would be expected under the null hypothesis. For any one of the significance tests, given that the null hypothesis is true, one expects 5 spurious rejections of the true null hypothesis out of 100 tests; thus, if an analyst keeps making F -tests within an experiment, he has more than a .05 probability of securing at least one statistically significant F , even if no actual effects exist. There are systematic ways to guard against this (see, for example, Pearson & Hartley 1954, pp. 39-40). At least, one should be suspicious of higher-order interactions that seem to be

significant at or near the .05 level. Many an experimenter utilizing a complex design has worked extremely hard trying to interpret a spuriously significant high-order interaction and in the process has introduced his fantasies into the journal literature.

Studies in which researchers do not manipulate any variables are common and important in the social sciences. These include opinion surveys, studies of variables related to injury in automobile accidents, and studies of the Hiroshima and Nagasaki survivors. ANOVA proves useful in many such investigations. [See Campbell & Stanley 1963; Lindzey 1954; see also EXPERIMENTAL DESIGN, article on QUASI-EXPERIMENTAL DESIGN.]

"Nesting" and repeated measurements. Many studies and experiments in the social sciences involve one or more factors whose levels do not "cross" the levels of certain other factors. Usually these occur in conjunction with repeated measurements taken on the same individuals. For example, if one classification is school and another is teacher within school, where each teacher teaches two classes within her school with different methods, then teachers are said to be "nested" within schools. Schools can interact with methods (a given method may work relatively better in one school than in another) and teachers can interact with methods *within schools* (a method that works relatively better for one teacher does not necessarily produce better results for another teacher in the same school), but schools cannot interact with teachers, because teachers do not "cross" schools—that is, the same teacher does not teach at more than one school.

This does not mean that a given teacher might not be more effective in another school but merely that the experiment provides no evidence on that point. One could, somewhat inconveniently, devise an experiment in which teachers did cross schools, teaching some classes in one school and some in another. But an experimenter could not, for example, have boys cross from delinquency to non-delinquency and vice versa, because delinquency-nondelinquency is a personal rather than an environmental characteristic. (For further discussion of nested designs see Brownlee [1960] 1965, chapters 13 and 15.)

If the order of repeated measurements on each individual is randomized, as when each person undergoes several treatments successively in random order, there is more likelihood that ANOVA will be appropriate than when the order cannot be randomized, as occurs, for instance, when the learning process is studied over a series of trials.

Complications occur also if the successive treatments have differential residual effects; taking a difficult test first may discourage one person in his work on the easier test that follows but make another person try harder. These residual effects seem likely to be of less importance if enough time occurs between successive treatment levels for some of the immediate influence of the treatment to dissipate. Human beings cannot have their memories erased like calculating machines, however, so repeated-measurement designs, although they usually reduce certain error terms because intraindividual variability tends to be less than interindividual variability, should not be used indiscriminately when analogous designs without repeated measurements are experimentally and financially feasible. (For further discussion see Winer 1962; Hays 1963, pp. 455–456; Campbell & Stanley 1963.)

Missing observations. For two factors with levels $s = 1, 2, \dots, S$ and $t = 1, 2, \dots, T$ in the experiment, such that the number of experimental units for the st th experimental combination is n_{st} , one usually designs the experiment so that $n_{st} = n$, a constant for all st . A few missing observations at the end of the experiment do not rule out a slightly adjusted simple ANOVA, if they were not caused differentially by the treatments. If, for example, one treatment was to administer a severe shock on several occasions, and the other was to give ice cream each time, it would not be surprising to find that fewer shocked than fed experimental subjects come for the final session. The outcome measure might be arithmetical-reasoning score; but if only the more shock-resistant subjects take the final test, comparison of the two treatments may be biased. There would be even more difficulty with, say, a male-female by shocked-fed design, because shocking might drive away more women than men (or vice versa).

When attrition is not caused differentially by the factors one may, for one-factor ANOVA, perform the usual analysis. For two or more factors, adjustments in the analysis are required to compensate for the few missing observations. (See Winer 1962, pp. 281–283, for example, for appropriate techniques.)

The power of the F -test. There are two kinds of errors that one can make when testing a null hypothesis against alternative hypotheses: one can reject the null hypothesis when in fact it is true, or one can fail to reject the null hypothesis when in fact it is false. Rejecting a true null hypothesis is called an "error of the first kind," or a "type I error." Failing to reject an untrue null hypothesis

is called an "error of the second kind" or "type II error." The probability of making an error of the first kind is called the *size* of the significance test and is usually signified by α . The probability of making an error of the second kind is usually signified by β . The quantity $1 - \beta$ is called the *power* of the significance test.

If there is no limitation on the number of experimental units available one can fix both α and β at any desired levels prior to the experiment. To do this some prior estimate of σ^2 is required, and it is also necessary to state what nonnull difference among the factor-level means is considered large enough to be worth detecting. This latter requirement is quite troublesome in many social science experiments, because a good scale of value (such as dollars) is seldom available. For example, how much is a one-point difference between the mean of style 1 and style 2 on a reading-comprehension test worth educationally? Intelligence quotients and averages of college grades are quasi-utility scales, although one seldom thinks of them in just that way. How much is a real increase in IQ from 65 to 70 worth? How much more utility for the college does a grade-point average of 2.75 (where $C = 2$ and $B = 3$) have than a grade-point average of 2.50? (For further discussion of this topic see Chernoff & Moses 1959.)

In the hypothetical printing-styles example (Tables 1 and 5) it is known that $\sigma^2 = 1$ and that the population mean of style 1 is one point greater than the population means of styles 2 and 3, so with this information it is simple to enter Winer's Table B.11 (1962, p. 657) with, for example, $\alpha = .05$ and $\beta = .10$ and to find that for each of the three styles $P = 20$ experimental units are needed.

In actual experiments, where σ^2 and the $\sum_{i=1}^k P_i \alpha_i^2$ of interest to the experimenter are usually not known, the situation is more difficult (see Brownlee [1960] 1965, pp. 97-111; McNemar [1949] 1962, pp. 63-69; Hays 1963; and especially Scheffé 1959, pp. 38-42, 62-65, 437-455).

Alternatives to analysis of variance

If one conducted an experiment to determine how well ten-year-old boys add two-digit numbers at five equally spaced atmospheric temperatures, he could use the techniques of regression analysis to determine the equation for the line that best fits the five means (in the sense of minimum squared discrepancies). This line might be of the simple form $\alpha + \beta T$ (that is, straight with slope β and intercept α) or it might be based on some other function of T . [See Winer 1962 for further discus-

sion of trend analysis; see also LINEAR HYPOTHESES, article on REGRESSION.]

The symmetrical two-tail t -test is a special case of the F -test; $t_{df}^2 = F_{1,df}$. Likewise, the unit normal deviate (z), called "critical ratio" in old statistics textbooks when used for testing significance, is a special case of F : $z^2 = F_{1,\infty}$. The F -distribution is closely related to the chi-square distribution. [For further discussion of these relationships, see DISTRIBUTIONS, STATISTICAL, article on SPECIAL CONTINUOUS DISTRIBUTIONS.]

For speed and computational ease, or when assumptions of ANOVA are violated so badly that results would seem dubious even if the data were transformed, there are other procedures available (see Winer 1962). Some of these procedures involve consecutive, untied ranks, whose means and variances are parameters dependent only on the number of ranks; an important example is the Kruskal-Wallis analysis of variance for ranks (Winer 1962, pp. 622-623). Other procedures employ the binomial expansion $(p + q)^n$ or the chi-square approximation to it for "sign tests." Still others involve dichotomizing the values for each treatment at the median and computing χ^2 . Range tests may be used also. [See Winer 1962, p. 77; McNemar (1949) 1962, chapter 19. Some of these procedures are discussed in NONPARAMETRIC STATISTICS.]

When the normal assumption is reasonable, there are often available testing and other procedures that are competitive with the F -test. The latter has factotum utility, and it has optimal properties when the alternatives of interest are symmetrically arranged relative to the null hypothesis. But when the alternatives are asymmetrically arranged, or in other special circumstances, competitors to F procedures may be preferable. Particularly worthy of mention are Studentized range tests (see Scheffé 1959, pp. 82-83) and half-normal plotting (see Daniel 1959).

Special procedures are useful when the alternatives specify an ordering. For example, in the style-of-type example it might be known before the experiment that if there is any difference between the styles, style 1 is better than style 2, and style 2 better than style 3 (see Bartholomew 1961; Chacko 1963).

It is also important to mention here the desirability of examining residuals (observations less the estimates of their expectations) as a check on the model and as a source of suggestions toward useful modifications. [See STATISTICAL ANALYSIS, SPECIAL PROBLEMS OF, article on TRANSFORMATIONS OF DATA; see also Anscombe & Tukey 1963.

Often an observed value appears to be so distant from the other values that the experimenter is tempted to discard it before performing an ANOVA. For a discussion of procedures in such cases, see STATISTICAL ANALYSIS, SPECIAL PROBLEMS OF, article on OUTLIERS.]

Multivariate analysis of variance. The analysis of variance is multivariate in the independent variables (the factors) but univariate in the dependent variables (the outcome measures). S. N. Roy (for example, see Roy & Gnanadesikan 1959) and others have developed a multivariate analysis of variance (MANOVA), multivariate with respect to both independent and dependent variables, of which ANOVA is a special case. A few social scientists (for example, Rodwan 1964; Bock 1963) have used MANOVA, but as yet it has not been used widely by workers in these disciplines.

III MULTIPLE COMPARISONS

Multiple comparison methods deal with a dilemma arising in statistical analysis: On the one hand, it would be unfortunate not to analyze the data thoroughly in all its aspects; on the other hand, performing several significance tests, or constructing several confidence intervals, for the same data compounds the error rates (significance levels), and it is often difficult to compute the over-all error probability.

Multiple comparison and related methods are designed to give simple over-all error probabilities for analyses that examine several aspects of the data simultaneously. For example, some simultaneous tests examine all differences between several treatment means.

Cronbach (1949, especially pp. 399-403) describes the problem of inflation of error probabilities in multiple comparisons. The solutions now available are, for the most part, of a later date (see Ryan 1959; Miller 1966). Miller's book provides a comprehensive treatment of the major aspects of multiple comparisons.

Normal means—confidence regions, tests

1. **Simultaneous limits for several means.** As a sample example of a situation in which multiple comparison methods might be applied, suppose that independent random samples are drawn from three normal populations with unknown means, μ_1, μ_2, μ_3 , but known variances, $\sigma_1^2, \sigma_2^2, \sigma_3^2$. If only the first sample were available, a 99 per cent confidence interval could be constructed for μ_1 :

$$(1) \quad \bar{X}_1 - 2.58\sigma_1/\sqrt{n_1} < \mu_1 < \bar{X}_1 + 2.58\sigma_1/\sqrt{n_1},$$

where \bar{X}_1 is the sample mean, and n_1 the size, of the first sample. In hypothetical repetitions of the procedure, the confidence interval covers, or includes, the true value of μ_1 99 per cent of the time in the long run. [See ESTIMATION, article on CONFIDENCE INTERVALS AND REGIONS.]

If all three samples are used, three statements like (1) can be made, successively replacing the subscript "1" by "2" and "3." The probability that all three statements together are true, however, is not .99 but $.99 \times .99 \times .99$, or .9703.

In a coordinate system with three axes marked μ_1, μ_2 , and μ_3 , the three intervals together define a 97 per cent (approximately) confidence box. This confidence box is shown in Figure 1. In order to obtain a 99 per cent confidence box—that is, to have all three statements hold simultaneously with probability .99—the confidence levels for the three individual statements must be increased. One

Figure 1 — A confidence box

method would be to make each individual confidence level equal to .9967, the cube root of .99.

The simple two-tail test of the null hypothesis (H_0) $\mu_1 = 0$ rejects it (at significance level .01) if the value 0 is not caught inside the confidence interval (1). It is natural to think of extending this test to the composite null hypothesis $\mu_1 = 0$ and $\mu_2 = 0$ and $\mu_3 = 0$ by rejecting the composite hypothesis if the point (0,0,0) is outside the confidence box corresponding to (1). The significance level of this procedure, however, is not .01 but $1 - .9703$, almost .03. In order to reduce the significance level to .01, "2.58" in (1) must be replaced by a higher number. If this is done symmetrically, the significance level for each of the three individual statements like (1) must be .0033. In this argument any hypothetical values of the means, $\mu_1^*, \mu_2^*, \mu_3^*$, may be used in place of 0,0,0 to specify the null hypothesis; the point $(\mu_1^*, \mu_2^*, \mu_3^*)$ then takes the place of (0,0,0).

The same principles can be applied just as easily to the case where the three variances are not known but are estimated from the respective samples, in which case 1 per cent points of Student's *t*-distribution take the place of 2.58. Of course, any other significance levels may also be used instead of 1 per cent.

Pooled estimate of variance. The problem considered so far is atypically simple because the three intervals are statistically independent, so that prob-

abilities can simply be multiplied. This is no longer true if the variances are unknown but are assumed to be equal and are estimated by a single pooled estimate of variance, $\hat{\sigma}^2$, which is the sum of the three within-sample sums of squares divided by $n_1 + n_2 + n_3 - 3$. This is equal to the mean square used in the denominator of an analysis-of-variance F [see LINEAR HYPOTHESES, article on ANALYSIS OF VARIANCE]. The conditions

$$\bar{X}_i - M\hat{\sigma}/\sqrt{n_i} < \mu_i < \bar{X}_i + M\hat{\sigma}/\sqrt{n_i}, \quad i = 1, 2, 3$$

(where M is a constant to be chosen), use the same $\hat{\sigma}$ and hence are not statistically independent. Thus, the probability that all three hold simultaneously is not the product of the three separate probabilities, although this is still a surprisingly good approximation, adequate for most purposes.

Critical values, M_α , have, however, been computed for $\alpha = .05$ and $.01$ and for any number of degrees of freedom ($n_1 + n_2 + n_3 - 3$) of $\hat{\sigma}^2$. If M_α is substituted for M in the three intervals, the probability that all three conditions simultaneously hold is $1 - \alpha$ (Tukey 1953).

Exactly the same principles described for the problem of estimating, or testing, three population means also apply to k means. A table providing critical values M_α for $k = 2, 3, \dots, 10$ and for various numbers of degrees of freedom, $N - k$, has been computed by Pillai and Ramachandran (1954). Part of the table is reproduced in Miller (1966). The square of M_α was tabulated earlier by Nair (1948a) for use in another context (see Section 7, below). This table is reproduced in Pearson and Hartley ([1954] 1966, table 19).

Notation. In the following exposition, " \bar{X}_i " and " μ_i " represent sample and population means, respectively ($i = 1, \dots, k$), " σ^2 " the population variance, generally assumed to be common to all k populations, " $\hat{\sigma}^2$ " the pooled sample estimate of σ^2 , and "SE" the estimated standard error of a statistic (SE will depend on $\hat{\sigma}^2$, on the particular statistic, and on the sample sizes involved). The symbol " \sum " always denotes summation over i , from 1 to k , unless otherwise specified; N denotes $\sum n_i$, the total sample size, and "ddf" stands for "denominator degrees of freedom," the degrees of freedom of $\hat{\sigma}^2$.

2. Treatments versus control (Dunnett). Many studies are concerned with the difference between means rather than with the means themselves. For example, sample 1 may consist of controls (that is, observations taken under standard conditions) to be used for comparison with samples 2, 3, \dots, k (taken under different treatments or nonstandard conditions), for the purpose of estimating the treatment effects, $\mu_2 - \mu_1, \dots, \mu_k - \mu_1$. For $k = 3, 4, \dots, 10$, for any number of denomi-

nator degrees of freedom, $N - k$, greater than 4, and for $\alpha = .05$ and $.01$, Dunnett (1955; also in Miller 1966) has tabulated critical values D_α such that with probability approximately equal to $1 - \alpha$, all $k - 1$ statements

$$|(\bar{X}_i - \bar{X}_1) - (\mu_i - \mu_1)| < D_\alpha SE, \quad i = 2, 3, \dots, k,$$

will be simultaneously true—that is, all $k - 1$ effects $\mu_i - \mu_1$ will be covered by confidence intervals centered at $\bar{X}_i - \bar{X}_1$ with half-lengths $D_\alpha SE$, where $SE = \sqrt{(1/n_i) + (1/n_1)} \hat{\sigma}$.

The over-all probability is exactly $1 - \alpha$ if all k sample sizes are equal. It is not the product of $k - 1$ probabilities (obtained from Student's t -distribution) of the separate confidence statements, because these are not statistically independent; dependence comes not only from the common estimator of σ in all statements but also from the correlation ($\rho \approx .5$ for sample sizes roughly the same) between any two differences $\bar{X}_i - \bar{X}_1$ with \bar{X}_1 in common. Surprisingly enough, the product rule gives a close approximation just the same.

Viewed as restrictions on the point (μ_1, μ_2, μ_3) in three-space, the two (pairs of) inequalities for $k = 3$ define a confidence region that is the intersection of the slab bounded by two parallel planes, $\mu_2 - \mu_1 = \bar{X}_2 - \bar{X}_1 \pm D_\alpha SE$, and another slab at 45° to the first slab. This is illustrated in Figure 2, where for simplicity all n_i are assumed to be equal. The region is a prism that is infinite in length, is parallel to the 45° line $\mu_1 = \mu_2 = \mu_3$, and has a rhombus as its cross section.

Dunnett's significance test rejects the null hypothesis, $H_0: \mu_1 = \dots = \mu_k = \mu$, in favor of the alternative hypothesis that one or more of the μ_i differ from μ_1 if the $k - 1$ confidence intervals do not all contain the value 0 or, equivalently, if

$$(2) \quad |t_{i1}| = |\bar{X}_i - \bar{X}_1|/SE \geq D_\alpha$$

for any i ($i = 2, \dots, k$). If the null hypothesis is of the less trivial form $\mu_i - \mu_1 = d_{i1}$, where the d_{i1} are any specified constants, then d_{i1} is subtracted from the differences of sample means in the numerators of t_{i1} .

The probability of rejecting H_0 if it is true, called the *error rate experimentwise*, is exactly the stated α if all sample sizes are equal, and is approximately α for unequal n_i , provided the inequality is not gross. Dunnett (1955) showed that a design using equal n_i , $i = 2, \dots, k$, but with n_1 larger in about the proportion $\sqrt{k-1} : 1$ is most efficient. Unfortunately this leads to true error rates exceeding the stated α if Dunnett's table is used, and it is then safer to substitute a Bonferroni t -statistic for Dunnett's D_α if k is as big as 6 or 10 (for Bonferroni t ,

Figure 2 — Confidence region for Dunnett method

see Section 14, below; see also Miller 1966, table 2).

Simultaneous one-tail tests are of the same form as (2), above, except that the absolute-value signs are removed and an appropriate smaller critical value, D_α , also tabulated in Dunnett (1955), is used. The corresponding confidence intervals are one-sided, extending to infinity on the other side.

3. All differences—Tukey method. In order to compare several means with one another rather than only with a single control, a method of Tukey's (1953) is suitable. It provides simultaneous confidence intervals (or significance tests, if desired) for all $\binom{k}{2} = \frac{1}{2}k(k-1)$ differences, $\mu_i - \mu_j$, among k means.

A constant, T_α , is chosen so that the probability is at least $1 - \alpha$ that all $\binom{k}{2}$ statements

$$|(\bar{X}_i - \bar{X}_j) - (\mu_i - \mu_j)| < T_\alpha SE,$$

or, equivalently,

$$|t_{ij}| = |(\bar{X}_i - \bar{X}_j) - (\mu_i - \mu_j)|/SE < T_\alpha,$$

will be simultaneously true. Here SE is equal to $\sqrt{(1/n_i) + (1/n_j)} \hat{\sigma}$. The probability is exactly $1 - \alpha$ if the sample sizes are equal (Tukey 1953; Kurtz 1956; Kramer 1956).

Simultaneous confidence intervals for all the differences, $\mu_i - \mu_j$, are centered at $\bar{X}_i - \bar{X}_j$ with half-

lengths $T_\alpha SE$. In a significance test of the null hypothesis, H_0 , that the differences, $\mu_i - \mu_j$, have any specified (mutually consistent) values, d_{ij} (often 0), one substitutes d_{ij} for $\mu_i - \mu_j$ in the t -ratios and rejects H_0 if the largest ratio is not less than T_α .

The constant, T_α , is $R_\alpha/\sqrt{2} = .707R_\alpha$, where R_α is the upper α -point in the distribution of the Studentized range. Table 29 of Pearson and Hartley ([1954] 1966) shows R_α for $\alpha = .1, .05$, and $.01$, for values of k up to 20, and for any number of ddf . Briefer tables are found in Vianelli (1959) and in a number of textbooks—for example, Winer (1962). More extensive tables prepared by Harter (1960) can also be found in Miller (1966).

Geometrically, Tukey's $(1 - \alpha)$ -confidence region can be obtained, for $k = 3$, by widening and thickening Dunnett's prism (Figure 2) in the proportion $T_\alpha : D_\alpha$ and then removing a pair of triangular prisms by intersection with a third slab. The cross section is hexagonal.

Tukey's multiple comparisons are frequently used after an F -test rejects H_0 but may also be used in place of F .

Simplified multiple t -tests. Simplified multiple t -tests, which were developed by Tukey, use the sum of sample ranges in place of σ and a critical value, T_α , adjusted accordingly. (See Kurtz et al. 1965.)

4. One outlying mean (slippage). In comparing k populations it may be desirable to find out whether one of them (which one is not specified in advance) is outstanding (has "slipped") relative to the others. Then using k independent treatment samples one may examine the differences, $\bar{X}_i - \bar{X}$, where $\bar{X} = \sum_{i=1}^k \sum_{j=1}^{n_i} X_{ij}/N = \sum n_i \bar{X}_i/N$. Let $\mu = \sum n_i \mu_i/N$.

Halperin provided critical values H_α such that with probability approximately $1 - \alpha$,

$$|(\bar{X}_i - \bar{X}) - (\mu_i - \mu)| < H_\alpha \sqrt{\frac{k}{k-1} \left(\frac{1}{n_i} - \frac{1}{N} \right)} \hat{\sigma}$$

simultaneously for $i = 1, \dots, k$ (Halperin et al. 1955). The probability is exactly $1 - \alpha$ in the case of equal n_i . This provides two-sided tests for the null hypothesis that all $\mu_i = \mu$ and simultaneous confidence intervals for all the $\mu_i - \mu$, in the usual way. In case the table is not at hand, a good approximation to the right-hand side of the inequality is (upper $(\alpha/2k)$ -point of Student's t) $\times \sqrt{(1/n_i) - (1/N)} \hat{\sigma}$.

Critical values for the corresponding one-sided test, to ascertain whether one of the means has slipped in a specified direction (for example, whether it has slipped down), were first computed by Nair (1952). David (1962a; 1962b) provides

improved tables. A refinement of Nair's test and of Halperin's is presented by Quisenberry and David (1961). In Pearson and Hartley ([1954] 1966), tables 26a and 26b (and the explanation on p. 51) pertain to these methods, whereas table 26 is Nair's statistic.

5. Contrasts—Scheffé method. A contrast in k population means is a linear combination, $\sum c_i \mu_i$, with coefficients adding up to zero, $\sum c_i = 0$. This is always equal to a multiple of the difference between weighted averages of two sets of means—that is, constant $\times (\sum a_i \mu_{a_i} - \sum b_i \mu_{b_i})$ with summations running over two subsets of the subscripts $(1, \dots, k)$ having no subscript in common and with $\sum a_i = 1, \sum b_i = 1$. The simple differences, $\mu_i - \mu_j$, are special contrasts. Some other examples include contrasts representing a difference between two groups of means (for example, $\frac{1}{2}[\mu_2 + \mu_3 + \mu_4] - \frac{1}{2}[\mu_1 + \mu_5]$) or slippage of one mean (for example, $\mu_2 - \bar{\mu}$, since this is equal to $[(k-1)/k]\mu_2 - [1/k][\mu_1 + \mu_3 + \mu_4 + \dots + \mu_k]$), or trend (for example, $-3\mu_1 - \mu_2 + \mu_3 + 3\mu_4$).

In an exploratory study to compare k means when little is known to suggest a specific pattern of differences in advance, any and all striking contrasts revealed by the data will be of interest. Also, when looking for slippage or simple differences one may wish to take account of some other, unanticipated, pattern displayed by the data.

Any of the systems of multiple comparisons discussed in sections 1–4 can be adapted to obtain tests, or simultaneous intervals, for all contrasts. For example, the $k-1$ simultaneous conditions $|(\bar{X}_i - \bar{X}_j) - (\mu_i - \mu_j)| < D_\alpha \sqrt{(1/n_i) + (1/n_j)} \hat{\sigma}$, where D_α represents the critical value of the Dunnett statistic as defined in Section 2, above, imply that every contrast, $\sum c_i \mu_i$, falls into an interval of half-length $D_\alpha \sum c_i^2 (1/n_i) \hat{\sigma}$, centered at $\sum c_i \bar{X}_i$, in the case of equal sample sizes.

The following method, developed by Scheffé, however, is more efficient for all-contrasts analyses, because it yields shorter intervals for most contrasts. Scheffé proved that

$$\sqrt{(k-1)F} = \max [\sum c_i (\bar{X}_i - \mu_i) / SE],$$

the largest of all the (infinitely many) Studentized contrasts, where F is the analysis-of-variance F -ratio for testing equality of all the μ_i , and where $SE = \sqrt{\sum (c_i^2/n_i)} \hat{\sigma}$. Thus,

$$\begin{aligned} 1 - \alpha &= \Pr\{F < F_\alpha\} \\ &= \Pr\{\text{all Studentized contrasts} < \sqrt{(k-1)F_\alpha}\} \\ &= \Pr\left\{\frac{\sum c_i (\bar{X}_i - \mu_i)}{SE} < \sqrt{(k-1)F_\alpha}\right. \\ &\quad \left.\text{for all sets of } c_i \text{ with } \sum c_i = 0\right\}. \end{aligned}$$

Simultaneous confidence intervals for all contrasts, $\sum c_i \mu_i$, are centered at $\sum c_i \bar{X}_i$ and have half-lengths $SE \sqrt{(k-1)F_\alpha}$. The confidence level is *exactly* the stated $1 - \alpha$, regardless of whether sample sizes are equal.

For $k = 3$, any particular interval can be depicted in (μ_1, μ_2, μ_3) -space by a pair of parallel planes equidistant from the line given by $\mu_1 - \bar{X}_1 = \mu_2 - \bar{X}_2 = \mu_3 - \bar{X}_3$ through the point $(\bar{X}_1, \bar{X}_2, \bar{X}_3)$. Together these planes constitute all the tangent planes of the cylinder (in the "variables" μ_1, μ_2, μ_3),

$$\sum n_i [(\bar{X}_i - \bar{X}) - (\mu_i - \mu)]^2 = (3-1)\hat{\sigma}^2 F_\alpha,$$

where F_α has degrees of freedom $3-1$ and $n-3$. This cylinder, like the prism of Figure 2, is infinite in length and equally inclined to the coordinate axes. (As in the case of the regions for Dunnett's and Tukey's procedures, the addition of the same constant to each of the coordinates X_1, X_2, X_3 of a point on the surface will move this point along the surface.) See Figure 3.

Significance test. A value of $F \geq F_\alpha$ implies $\sum c_i (\bar{X}_i - \mu_i) \geq SE \sqrt{(k-1)F_\alpha}$ for at least one contrast (namely, at least for the maximum Studentized contrast). Scheffé's multiple comparison test declares $\sum c_i \bar{X}_i$ to be statistically significant—that is, $\sum c_i \mu_i$ different from zero—for all those con-

Figure 3 — Confidence region for all contrasts (Scheffé)

trasts for which the inequality is true. Thus, one may test every contrast of interest, or every contrast that looks promising, and incur a risk of just α of falsely declaring any $\sum c_i \mu_i$ whatsoever to be different from zero; in other words, the probability of making no false statement of the form $\sum c_i \mu_i \neq 0$ is $1 - \alpha$, the probability of making one or more such statements is α . Of course, the Scheffé approach gives a larger confidence interval (or decreased power) than the analogous procedure if only a single contrast is of interest.

General linear combinations. Simultaneous confidence intervals, or tests, can also be obtained for all possible linear combinations, $\sum c_i \mu_i$, with the restriction $\sum c_i = 0$ lifted. Then Scheffé's confidence and significance statements for contrasts remain applicable, except that $(k-1)F_\alpha$ is changed to kF_α and the numerator degrees of freedom of F are changed from $k-1$ to k . (See Miller 1966, chapter 2, sec. 2).

A confidence region for all (standardized) linear combinations consists of the ellipsoid in the k -dimensional space with axes labeled $\mu_1, \mu_2, \dots, \mu_k$, $\sum n_i (\bar{X}_i - \mu_i)^2 < kF_\alpha \hat{\sigma}^2$. For $k=3$, any particular interval can be depicted in (μ_1, μ_2, μ_3) -space by a pair of parallel planes equidistant from the point $(\bar{X}_1, \bar{X}_2, \bar{X}_3)$. Together these planes constitute all the tangent planes of the confidence ellipsoid (in the "variables" μ_1, μ_2, μ_3).

Tukey (1953) and Miller (1966) also discuss the generalization of the application of intervals based on the Studentized range (referred to in Section 3, above) to take care of all linear combinations. Simultaneous intervals for all linear combinations can also be based on the Studentized maximum modulus (Section 1); half-lengths become $M_\alpha \sqrt{1/n} \hat{\sigma} \cdot \sum |c_i|$ (Tukey 1953).

All of these methods dealing with contrasts and general linear combinations are described in Miller (1966).

Further discussion of normal populations

6. Newman-Keuls and Duncan procedures. The Newman-Keuls procedure is a multiple comparison test for all differences. It does not provide a confidence region. The sample means are arranged and renumbered in order of magnitude, so that $\bar{X}_1 < \bar{X}_2 < \dots < \bar{X}_k$. The first step is the same as Tukey's test; the null hypothesis is rejected or accepted according as $\bar{X}_k - \bar{X}_1$, the range of the sample means, is \geq or $< T_{\alpha, k} SE$, where $T_{\alpha, k}$ is the upper α -point of Tukey's statistic for k means and $N - k$ ddf.

Accepting H_0 means that there is not enough evidence to establish differences between any of

the population means, and the analysis is complete (all k means are then called "homogeneous"). On the other hand, if the null hypothesis is rejected, so that μ_k , the population mean corresponding to the largest sample mean, is declared to be different from μ_1 , the population mean corresponding to the smallest sample mean, the next step is to test $\bar{X}_{k-1} - \bar{X}_1$ and $\bar{X}_k - \bar{X}_2$ similarly, but with $T_{\alpha, k-1}$ in place of $T_{\alpha, k}$ (the original pooled variance estimator $\hat{\sigma}^2$ and $N - k$ ddf are used throughout). A sub-range of means that is not found statistically significant is called homogeneous. As long as a sub-range is statistically significant, the two sub-ranges obtained by removing in one case its largest and in the other case its smallest \bar{X}_i are tested, using a critical value $T_{\alpha, h}$, where h is only the number of means left in the new sub-ranges—but testing is limited by the rule that every sub-range contained in a homogeneous range of means is not tested but is automatically declared to be homogeneous. The result of the whole procedure is to group the means into homogeneous sets, which may also be represented diagrammatically by connecting lines, as in the example presented in Section 10, below.

Critics of the Newman-Keuls method object that the error probabilities, such as that of falsely declaring $\mu_2 \neq \mu_3$, are not even known in this test; its supporters, however, argue that power should not be wasted by judging sub-ranges by the same stringent criterion used for the full range of all k sample means.

Duncan (1955) goes a step further, arguing that even $T_{\alpha, h}$ is too stringent a criterion because the $\frac{1}{2}h(h-1)$ differences between h means have only $h-1$ degrees of freedom. He concludes that $T_{\gamma, h}$ should be used instead, where $1 - \gamma = (1 - \alpha)^{h-1}$. This further increases the power—and the effective type I error probability. For a study of error rates of Tukey, Newman-Keuls, Duncan, and Student tests, see Harter (1957).

7. General Model 1 design. The F -test in the one-way analysis of variance and the multiple comparison methods already discussed are based on the fact that ddf times $\hat{\sigma}^2/\sigma^2$ has a chi-square distribution and is independent of the sample means. This condition is also satisfied by the residual variance used in randomized blocks, factorial designs, Latin squares, and all Model 1 designs. Therefore, all these designs permit the use of the methods, and tables, of sections 1-6, to compare the means defined by any one factor, provided that these are independent.

In certain instances of nonparametric multiple comparisons and in certain instances of multiple comparisons of interactions in balanced factorial

designs, where the (adjusted or transformed) observations are not independent but equicorrelated, the multiple comparison methods of sections 2-6 still apply: The use of the adjusted error variance, $(1-\rho)\hat{\sigma}^2$, to compute standard errors fully compensates for the effect of equal correlations (see Tukey 1953; Scheffé 1953; Miller 1966, pp. 41-42, 46-47). Scheffé's method can also be adapted for use with unequal correlations (see Miller 1966, p. 53).

When several factors, and perhaps some interactions, are *t*-tested in the same experiment, the question arises whether extra adjustment should not be made for the resulting additional compounding of error probabilities. One method open to an experimenter willing to sacrifice power for strict experimentwise control of type 1 error is the conservative one of using error rates per *t*-test of $\alpha/(\text{number of } t\text{-tests contemplated})$, that is, using Bonferroni *t*-statistics (see Section 14). For experimentwise control of error rates in the special case of a 2^r factorial design, Nair (1948a) has tabulated percentage points of the largest of r independent χ^2 's with one degree of freedom, divided by an independent variance estimator (Pearson & Hartley [1954] 1966, table 19). The statistic is equal to the square of the Studentized maximum modulus introduced in Section 1.

8. An example—juxtaposition of methods. Three competing theories about how hostility evoked in people by willfully imposed frustration may be diminished led Rothaus and Worchel (1964) to goad 192 experimental subjects into hostility by unfair administration of a test of coordination and then to apply the following "treatments" to four groups, each composed of 48 subjects: (1) no treatment (control); (2) fair readministration of the test, seemingly as a result of a grievance procedure (instrumental communication); (3) an opportunity for verbal expression of hostility (catharsis); (4) conversation to the effect that the test was unfair and the result therefore not indicative of failure on the subjects' part (ego support). After treatment all subjects were given another—

Table 1 — Analysis of variance of hostility scores

Source	df	Mean square	F-ratio
4 treatments	3	369.77	3.38*
3 subgroups	2	151.31	1.38
2 sexes	1	41.14	0.38
2 BIHS levels	1	2.68	0.02
All the interactions, none of them statistically significant	40		
4 replications (nested)	144	109.54 = $\hat{\sigma}^2$	

* Denotes statistical significance at the 5 per cent level.

fair—test of coordination. Each treatment group was subdivided into three subgroups, a different experimenter working with each subgroup. All subjects had been given Behavioral Items for Hostility Scales (BIHS) three weeks before the experiment.

The experimental plan was factorial: 4 treatments \times 3 subgroups \times 2 sexes \times 2 BIHS score groups (high versus low) \times 4 replications. The study variable, *X*, was hostility measured on the Social Sensitivity Scale at the end of the experiment.

The sample means (unordered) for the four treatment groups were $\bar{x}_1 = 47.08$, $\bar{x}_2 = 42.00$, $\bar{x}_3 = 48.53$, $\bar{x}_4 = 45.40$.

In fact, the numbers in Table 1 reflect an analysis of covariance. The mean squares shown are adjusted mean squares, the sample means are adjusted means, and $\hat{\sigma}^2$ has 143 df. But for the sake of simplicity of interpretation the data will be treated as if they had come from a $4 \times 3 \times 2 \times 2$ factorial analysis of variance. The estimated standard error for differences between two means, SE, is $\sqrt{[(1/48) + (1/48)] \times 109.54} = 2.136$.

Dunnett comparisons. The Dunnett method, with $\alpha = .05$, would be applied to the data of the experiment, as analyzed in Table 2. As indicated in Table 2, the one-tail test in the direction of the theory (H_1) under study declares μ_2 to be less than μ_1 . Thus, the conclusion, if the one-sided Dunnett test and the 5 per cent significance level are adopted, is that instrumental communication reduces hostility but that the evidence does not confirm any reduction due to ego support or catharsis. If the two-tail test had been chosen, allowing for

Table 2 — Dunnett comparisons of control with three treatments, $\alpha = .05$

Pair	$\bar{x}_i - \bar{x}_j$	DUNNETT METHOD: TWO-SIDED			DUNNETT METHOD: ONE-SIDED

* Statistically significant at the 5 per cent level; all other pairs do not reach statistical significance at the 5 per cent level.

a possible increase in hostility due to treatment, the conclusion would be that there is insufficient evidence to reject.

All pairs—Tukey and Scheffé methods. A comparison of all possible pairs of means by the methods of Tukey and Scheffé is shown in Table 3. The tests of Tukey and Scheffé in this case both discount $\bar{x}_1 - \bar{x}_3$ but declare $\bar{x}_2 - \bar{x}_3$ "significant." The conclusion is that instrumental communication leaves the mean hostility of frustrated subjects lower than ego support does, but no other difference is established; specifically, neither test would conclude that instrumental communication actually reduces hostility as compared with no treatment or that ego support increases (or reduces) it.

In addition to the simple differences, the data suggest testing a contrast related to the alternate hypothesis $\mu_2 < \mu_3 < \mu_1 < \mu_4$, for example, the contrast $-3\mu_2 - \mu_3 + \mu_1 + 3\mu_4$. (It is legitimate, for these procedures, to choose such a contrast after inspecting the data.) For the present example, $-3\bar{x}_2 - \bar{x}_3 + \bar{x}_1 + 3\bar{x}_4 = 21.27$; the SE for a Scheffé test is $\sqrt{(3^2 + 1^2 + 1^2 + 3^2)/48\hat{\sigma}^2} = \sqrt{10} \times 2.136 = 6.755$, and $t = 21.27/6.755 = 3.15$, statistically significant at the 5 per cent level ($3.15 > 2.80$). The conclusion is that $\mu_2 \leq \mu_3 \leq \mu_1 \leq \mu_4$ with at least one strict inequality holding. A Scheffé 95 per cent confidence interval for $-3\mu_2 - \mu_3 + \mu_1 + 3\mu_4$ is (1.36, 40.18). A Tukey test would not find this contrast statistically significant. For this analysis 2.136 is multiplied by $\frac{1}{4}(|-3| + |-1| + |1| + |3|) = 4$, instead of by $\sqrt{10}$, yielding 8.544. Thus, in this case $t = 21.27/8.544 = 2.49$, which is less than 2.60, and a confidence interval is (-0.94, +43.48).

The SE for individual \bar{x}_i , also used in slippage statistics, is $\sqrt{(1/48)\hat{\sigma}^2} = 2.136/\sqrt{2} = 1.510$. For $k = 4$, $M_{05} = 2.50$, and simultaneous confidence intervals for the four μ_i are centered at the \bar{x}_i and have half-lengths $2.50 \times 1.51 = 3.78$.

The 5 per cent critical value tabulated by Halperin et al. for two-sided slippage tests is 2.23;

thus $(\bar{x}_2 - \bar{x})/1.51 = 2.48$ is statistically significant, whereas the other three t -ratios for slippage are not. The conclusion of this test would be that mean hostility after instrumental communication is low compared with that after other treatments; no other treatment can be singled out as leaving hostility either low or high compared with that after other treatments.

An example of Newman-Keuls and Duncan tests is given in Section 10, below.

Other multiple comparison methods

9. Nonparametric multiple comparisons. The multiple comparison approach has been articulated with nonparametric (or distribution-free) methods in several ways [for background see NONPARAMETRIC STATISTICS].

For example, one of the simplest nonparametric tests is the sign test. Suppose that an experiment concerning techniques for teaching reading deals with school classes and that each class is divided in half at random. One half is taught by method 1, the other by method 2, the methods being allocated at random. Suppose further that improvement in average score on a reading test after two months is the basic observation but that one chooses to consider only whether the pupils taught by method 1 gain more than the pupils taught by method 2, or vice versa, and not the magnitude of the difference. If C is the number of classes for which the pupils taught with method 1 have a larger average gain than those taught with method 2, then the (two-sided) sign test rejects the null hypothesis of equal method effect when the absolute value of C is larger than a critical value. The critical value comes simply from a symmetrical binomial distribution.

Suppose now that there are k teaching methods, where k might be 3 or 4, and the classes are each divided at random into k groups and assigned to methods. Let C_{ij} ($i \neq j$) be the number of classes

for which the average gain in reading-test score for the group taught by method i is greater than that for the group taught by method j . Each C_{ij} taken separately has (under the null hypothesis that the corresponding two methods are equally effective) a symmetric binomial distribution which is approximated asymptotically by $\frac{1}{2}n + z\frac{1}{2}\sqrt{n} + \frac{1}{2}$, where n is the number of classes, z is a standard normal variable, and $\frac{1}{2}$ is a continuity correction. But to test for the equality of all k methods, the largest $|C_{ij}|$ should be used. The critical values of this statistic may be approximated by $T_{\alpha}\frac{1}{2}\sqrt{n} + \frac{1}{2}$, where T_{α} is the upper α point for Tukey's statistic with k groups and $ddf = \infty$.

The same procedure is feasible for other two-sample test statistics—for example, rank sums. An analogous method works for comparing $k - 1$ treatments with a control; in the teaching-method experiment, if method 1 were the control, this would mean using as the test statistic the maximum over $j \neq 1$ of $|C_{1j}|$ (or of C_{1j} in the one-sided case). For a discussion of this material, see Steel (1959).

Joint nonparametric confidence intervals may sometimes be obtained in a similar way. Given a confidence interval estimation procedure related to any two-sample test statistic with critical value S_{α} (see Moses 1953; 1965), the same procedure with S_{α} replaced by its multiple comparison analogue C_{α} yields confidence intervals with a joint confidence level of $1 - \alpha$.

A second class of nonparametric multiple comparison tests arises by analogy with normal theory analysis of variance for the one-way classification and other simple designs [see LINEAR HYPOTHESES, article on ANALYSIS OF VARIANCE]. The procedures start by transforming the observations into ranks

or other kinds of simplified scores (except that the so-called permutation tests leave the observations unaltered). The analysis is conditional on the totality of scores and uses as its null distribution that obtained from random allocations of the observed scores to treatments. The test statistic may be the ordinary F -ratio on the scores, but modified so that the denominator is the exact over-all variance of the given scores. This statistic's null distribution is approximately F , with $k - 1$ and ∞ as degrees of freedom (where k is the number of treatments), or, equivalently, $k - 1$ times the F -test statistic has as approximate null distribution the chi-square distribution with $k - 1$ degrees of freedom. Similar adaptations hold for the Tukey test statistic and others. The approach may also be extended to randomized block designs; in another direction, the approach may be extended to compare dispersion, rather than location. Discussions of this material are given by Nemenyi (1963) and Miller (1966, chapter 2, sec. 1.4, and chapter 4, sec. 7.5).

A difficulty with these test procedures is that confidence sets cannot generally be obtained in a straightforward way.

A third nonparametric approach to multiple comparisons is described by Walsh (1965, pp. 535–536). The basic notion applies when there are a number of observations for each treatment or treatment combination. Such a set of observations is divided into several subsets; the average of each subset is taken. These averages are then treated by normal theory procedures of the kind discussed earlier.

For convenient reference, a few 5 per cent and 1 per cent critical points of multiple comparison statistics with $ddf = \infty$ are listed in Table 4.

Table 4 — Selected 5 per cent and 1 per cent critical points of multiple comparison statistics with $ddf = \infty$

k	DUNNETT $k-1$ versus one		TUKEY all pairs	NAIR-HALPERIN outlier tests		SCHEFFÉ $\sqrt{X_{k-1}^2}$	DUNCAN

10. An example. As an illustration of some distribution-free multiple comparison methods, consider the following data from Vaughan, Sjöberg, and Smith (1966), who sent questionnaires to a sample of scientists listed in *American Men of Science* in order to compare scientists in four different fields with respect to the role that traditional religion plays in their lives. Table 5 summarizes responses to the question about frequency of church attendance and shows some of the calculations.

Using the data of Table 5, illustrative significance tests of the null hypothesis of four identical population distributions, against various alternatives, will be performed at the 1 per cent level.

The method of Yates (1948) begins by assigning ascending numerical scores, u , to the four ordered categories; arithmetically convenient scores, as shown in the last column of Table 5, are -1, 0, 1, and 2. Sample totals of scores are calculated—for example, $T_1 = 44(-1) + 38(0) + 52(1) + 33(2) = 74$, and the average score for sample i is $\bar{u}_i = T_i/n_i$. From the combined sample (margin) Yates computes an average score, $\bar{u} = T/N = .210$, and the variance of scores,

$$\sigma^2 = \frac{N}{N-1} (\text{average square} - \bar{u}^2),$$

giving $(638/637)\{[247(1) + 108(0) + 185(1) + 98(4)]/638 - .210^2\} = 1.2494$.

Yates then computes a variance between means, $T_1^2/n_1 + \dots + T_4^2/n_4 - T^2/N = 17.05$, and the critical ratio used is either $F = (17.05/3)/1.2494$ or $\chi^2 = 17.05/1.2494 = 13.7$. The second of these is referred to a table of chi-square with 3 df and found significant at the 1 per cent level (in fact, $P = .0034$).

It follows that some contrasts must be statistically significant. The almost linear progression of the sample mean scores suggests calculating $3\bar{u}_1 + \bar{u}_2 - \bar{u}_3 - 3\bar{u}_4 = 1.438$. For the denominator, $(3^2/167 + 1^2/159 + 1^2/155 + 3^2/157)\sigma^2 = .1240 \times 1.2494 = .1549$, so that $\chi^2 = 1.438^2/.1549 = 13.35$, or its square root, $z = 1.438/\sqrt{.1549} = 3.65$. (This comes close to the value $\sqrt{13.7} = 3.70$ of the largest standardized contrast—see Section 5.) When 3.65 is referred to the Scheffé table (in Table 4, above) for $k = 4$, or when 13.35 is referred to a table of chi-square with 3 df , each is found to be statistically significant (in fact, $P = .0040$). The conclusion that can be drawn from this one-sided test for trend is that the population mean scores are ordered $\bar{\mu}_1 \geq \bar{\mu}_2 \geq \bar{\mu}_3 \geq \bar{\mu}_4$ with at least one strict inequality holding. Had a trend in this particular order been predicted ahead of time and postulated as the sole alternative hypothesis to be considered, $z = 3.65$ could have been judged by the normal table, yielding $P = .00013$. The two-tail version of this test is Yates's one-degree-of-freedom chi-square for trend (1948).

Another contrast that may be tested is the simple difference $\bar{u}_1 - \bar{u}_4 = .443 - .000$. Here $SE = \sqrt{[(1/167) + (1/157)] \times 1.2494} = .1243$, and $z_{14} = .443/.1243 = 3.57$. Because it is greater than 3.37, this contrast is statistically significant. Similarly, $z_{13} = (.443 - .136)/.1239 = 2.48$, but this is not significant at the 1 per cent level, and the other simple differences are still smaller.

If Tukey's test had been adopted instead of Scheffé's, the same ratios would be compared with the critical value 3.11 ($k = 4$, $\alpha = .01$). The conclusions would be the same in the present case. Tukey's method could also be used to test other contrasts.

In the present example, the Newman-Keuls procedure would also have led to the same conclusions about simple differences: $z_{14} = 3.57$ is called significant because it is greater than 3.11; then z_{13} (which equals 2.48) and z_{24} (which is still smaller) are compared with 2.91 and found "not significant," and the procedure ends. The conclusions may be summarized as follows:

.443 .245 .136 .000,

where the absence of a line connecting \bar{u}_i with \bar{u}_j signifies that $\bar{\mu}_i$ and $\bar{\mu}_j$ are declared unequal. It may be argued that a conclusion of the form "A, B, and C homogeneous, B, C, and D homogeneous, but A, B, C, and D not homogeneous" is self-contradictory. This is not necessarily the case if the interpretation is the usual one that A, B, and C *may* be equal (not enough evidence to prove them unequal) and B, C, and D may be equal, but A and D are not equal.

In Duncan's procedure the critical value 3.11 used in the first stage would be replaced by 2.76 (see Table 5), and the critical value 2.91 used at the second stage ($k = 3$) would be replaced by 2.68. Since $3.57 > 2.76$ but $2.48 < 2.68$, Duncan's test leads to the same conclusion in the present example as the Newman-Keuls procedure.

A Halperin outlier test would use $\max |\bar{u}_i - \bar{u}|$, in this case $.443 - 2.10 = .233$, divide it by

$$\sqrt{4/3[(1/167) - (1/638)]} 1.2494 = .08582,$$

and compare the resulting ratio, 2.72, with the critical value, 2.61 ($k = 4$, 1 per cent level). The next largest ratio is $(.210 - .000)/.08944 = 2.35$. The conclusion is that chemical engineers tend to report more frequent church attendance than the other groups, but nothing can be said about geologists. If the outlier contrasts had been tested as part of a Scheffé test for all contrasts, none of them would have been found significant at the 1 per cent level (critical value 3.37) or even at the 5 per cent level.

What would happen if unequally spaced scores had been used instead of $-1, 0, 1, 2$ to quantify the four degrees of religious loyalty? In fact, Vaughan and his associates described the ordered categories not verbally but as frequency of church attendance per month grouped into 0, 1, 2-4, 5+. Although we do not know whether frequency of church attendance is a linear measure of the importance of religion in a person's life, the scores (0, 1, 3, 6) could reasonably have been assigned. In the present case this would lead to essentially the same conclusions that the other scoring led to: The mean scores become 2.35, 2.08, 1.82, and 1.57, Yates's

χ^2 changes from 13.7 to 12.5, the standardized contrast for trend changes from $\sqrt{13.35}$ to very nearly $\sqrt{12.5}$, z_{14} changes from 3.57 to 3.36, and z_{13} and z_{24} again have values too small for statistical significance by Tukey's criterion or by Newman-Keuls'.

A fundamentally different assignment of scores—for example, 1, 0, 0, 1—would be used to test for differences in spread. It yields sample means, \bar{u}_i , of .461, .591, .548, .576, $\bar{u} = 0.541$ and a variance, σ^2 , of .2484. Yates's analysis-of-variance χ^2 is $1.449/0.2484$, that is, only 5.83, so $P = .12$. Thus, no contrast is called significant in a Scheffé test (or, it turns out, in any other multiple comparison test at the 1 per cent significance level). In the present example these tests for spread are unreliable, because the presence of sample location differences, noted above, can vitiate the results of the test for differences in spread.

Throughout the numerical calculations in this section, the continuity correction has been neglected. In the case of unequal sample sizes it is difficult to determine what continuity correction would yield the most accurate results, and the effect of the adjustment would be slight anyway. When sample sizes are equal, the use of $|T_i - T_j| - \frac{1}{2}$ in place of $|T_i - T_j|$ is recommended, as it frequently (although not invariably) improves the fit of the asymptotic approximation used.

11. Comparisons for differences in scale. Stand- and multiple comparisons of variances of k normal populations, by Cochran (1941), David (1952), and others, utilize ratios of the $\hat{\sigma}_i^2$. These methods should be used with caution, because they are ultra-sensitive to slight nonnormality.

Distribution-free multiple comparison tests for scale differences are also available. Any rank test may be used with a Siegel-Tukey reranking [see NONPARAMETRIC STATISTICS, article on RANKING METHODS]. Such methods, too, require caution, because—especially in a joint ranking of all k samples—any sizable location differences may masquerade as differences in scale (Moses 1963).

Safer methods—but with efficiencies of only about 50 per cent for normal distributions—are adaptations of some tests by Moses (1963). In these tests a small integer, s , such as 2 or 3, is chosen, and each sample is randomly subdivided into subgroups of s observations. Let y be the range or variance of a subgroup. Then any multiple comparison tests may be applied to the k samples of y 's (or $\log y$'s), at the sacrifice of between-subgroups information. The effective sample sizes have been reduced to $[n_i/s]$; if these are small (about 6), either a nonparametric test or, at any rate, $\log y$'s

should be used. (Some nonparametric multiple comparison tests, such as the median test, have no power—that is, they cannot possibly reject the null hypothesis—at significance levels such as .05 with small samples. But rank tests can be used with several samples as small as 4 or 5.)

12. **Multiple comparisons of proportions.** A simultaneous test for all differences between k proportions p_1, \dots, p_k , based on large samples, can be obtained by comparing

$$\text{Max} \frac{X_i/n_i - X_j/n_j}{\sqrt{\frac{N}{N-1} \left(\frac{1}{n_i} + \frac{1}{n_j} \right) \frac{X}{N} \left(1 - \frac{X}{N} \right)}}$$

with a critical value of Tukey's statistic (Section 3), where X_i , $i = 1, \dots, k$, denotes the number of "successes" in sample i and $X = \sum X_i$. Analogous asymptotic tests can be used for comparison of several treatments with a control and other forms of multiple comparisons. If X/N is small, the sample sizes must be very large for this asymptotic approximation to be adequate. (For a similar method see Ryan 1960.)

Small-sample multiple comparison tests of proportions may be carried out by transforming the counts into normal variables with known equal variances and then applying any test of sections 1-7 to these standardized variables (using ∞ *ddf*). [See STATISTICAL ANALYSIS, SPECIAL PROBLEMS OF, article on TRANSFORMATIONS OF DATA; see also Siotani & Ozawa 1958.]

A $(1 - \alpha)$ -confidence region for k population proportions is composed of a $\sqrt{1 - \alpha}$ -confidence interval for each of them. Simultaneous confidence intervals for a set of differences of proportions may be approximated by using Bonferroni's inequality (see Section 14). For a discussion of confidence regions for multinomial proportions, see Goodman (1965).

Some discussion of multiple comparisons of proportions can be found in Walsh (1965, for example, pp. 536-537).

13. **Selection and ranking.** The approach called selection or ranking assumes a difference between populations and seeks to select the population(s) with the highest mean—or variance or proportion—or to arrange all k populations in order [see SCREENING AND SELECTION; see also Bechhofer 1958], Bechhofer, Kiefer, and Sobel (1967) have written a monograph on the subject.

Error rates, choice of method, history

14. **Error rates and choice of method.** In a significance test comparing two populations, the significance level is defined as

$$\alpha = \frac{\text{number of type I errors}}{\text{number of comparisons when } H_0 \text{ is true}}$$

in repeated use of the same criterion. This is termed the *error rate per comparison*. The corresponding confidence level for confidence intervals is $1 - \alpha$.

For analyses of k -sample experiments one may instead define the *error rate per experiment*,

$$\alpha' = \frac{\text{number of type I errors}}{\text{number of experiments analyzed, when } H_0 \text{ is true}}.$$

This is related to what Miller (1966) terms the "expected error rate." For m (computed or implied) comparisons per experiment, $\alpha' = m\alpha$; $\alpha = \alpha'/m$ (see Stanley 1957).

Standard multiple comparison tests specify an *error rate experimentwise* (or "familywise"):

$$\alpha = \frac{\text{number of experiments, when } H_0 \text{ is true, leading to any type I errors,}}{\text{number of experiments analyzed, when } H_0 \text{ is true}}.$$

Miller refers to this as the "probability of a non-zero family error rate" or "probability error rate."

The only difference between α' and α is that α counts multiple rejections in a single experiment as only one error whereas α' counts them as more than one. Hence, $\alpha \leq \alpha'$; this is termed *Bonferroni's inequality*.

On the other hand, it is also true that unless α' is large, α is almost equal to α' , so that α and α' may be used interchangeably for practical purposes. For example, D_6 for 6 treatments and a control, M_6 for $k = 6$, and T_6 for $k = 4$ ($\binom{4}{2} = 6$), are all approximately equal to the two-tailed critical value $|t|_{\alpha/4} = t_{\alpha/12}$ of Student's t . More generally, m individual comparisons may safely be made using any statistic at significance level α/m per comparison when it is desired to avoid error rates greater than α experimentwise; this procedure may be applied to comparisons of several correlation coefficients or other quantiles for which multiple comparison tables are not available. Only when α is about .10 or more, or when m is very big, does this lead to serious waste. Then α' grossly overstates α , power is lost, and confidence intervals are unnecessarily long (see Stanley 1957; Ryan 1959; Dunn 1961).

Some authors refer to (α/m) -points as Bonferroni statistics and to their use in multiple comparisons as the Bonferroni method. Table 2 in Miller (1966) shows Bonferroni t -statistics, $(.05/2m)$ -points of Student's t for various m and various numbers of *ddf*.

Bonferroni's second inequality (see Halperin

et al. 1955, p. 191) may sometimes be used to obtain an upper limit for the discrepancy $\alpha' - \alpha$ and a second approximation to critical values for error rates α experimentwise. This works best in the case of slippage statistics and was used by Halperin and his associates (1955), Doornbos and Prins (1958), Thompson and Willke (1963), and others.

The choice between "experimentwise" and "per comparison" is largely a matter of taste. An experimenter should make it consciously, aware of the implications: A given error probability, α , per comparison implies that the risk of at least one type I error in the analysis is much greater than α ; indeed, about $\alpha \times m$ such errors will probably occur.

Perhaps analyses reporting error rates experimentwise are generally the most honest, or transparent. However, too dogmatic an application of this principle would lead to all sorts of difficulties. Should not the researcher who in the course of his career analyzes 86 experiments involving 1,729 relevant contrasts control the error rate *lifetime-wise*? If he does not, he is almost bound to make a false positive inference sooner or later.

Sterling (1959) discusses the related problem of concentration of type I errors in the literature that result from the habit of selecting significant findings for publication [see FALLACIES, STATISTICAL, for further discussion of this problem].

There is another context in which the problem of choosing error rates arises: If an experimenter laboriously sets up expensive apparatus for an experiment to compare two treatments or conditions in which he is especially interested, he often feels that it would be unfortunate to pass up the opportunity to obtain additional data of secondary interest at practically no extra cost or trouble; so he makes observations on populations 3, 4, ..., k as well. It is then possible that the results are such that a two-sample test on the data of primary interest would have shown statistical significance, but no "significant differences" are found in a multiple comparison test. If the bonus observations thus drown out, so to speak, the significant difference, was the experimenter wrong to read them? He was not—the opportunity to obtain extra information should not be wasted, but the analysis should be planned ahead of time with the experimenter's interests and priorities in mind. He could decide to analyze his primary and subsidiary results as if they had come from separate experiments, or he could conduct multiple comparisons with an overall error rate enlarged to avoid undue loss of power,

or he could use a method of analysis which subdivides α , allocating a certain (large) part to the primary comparison and the rest to "data snooping" among the extra observations (Miller 1966, chapter 2, sec. 2.3).

Whenever it is decided to specify error rates experimentwise, a choice between different systems of multiple comparisons (different shapes of confidence regions) remains to be made. In order to study simple differences or slippage only, one of the methods of sections 2–4 above (or a nonparametric version of them) is best—that is, yields the shortest confidence intervals and most powerful tests, provided the n_i are (nearly) equal. But Scheffé's approach (see section 5) is better if a variety of contrasts may receive attention.

When sample sizes are grossly unequal, probability statements based on existing Tukey or Dunnett tables, computed for equal n 's, become too inaccurate. Pending the appearance of appropriate new tables, it is better to use Scheffé's method, which furnishes exact probabilities. The Bonferroni statistics discussed above offer an alternative solution, preferable whenever attention is strictly limited to a few contrasts chosen ahead of time. Miller (1966, especially chapter 2, secs. 2.3 and 3.3) discusses these questions in some detail.

15. History of multiple comparisons. An early, isolated example of a multiple comparison method was one developed by Working and Hotelling (1929) to obtain a confidence belt for a regression line (see Miller 1966, chapter 3; Kerrich 1955). This region also corresponds to simultaneous confidence intervals for the intercept and slope [see LINEAR HYPOTHESES, article on REGRESSION]. Hotelling (1927) had already developed the idea of simultaneous confidence interval estimation earlier in connection with the fitting of logistic curves to population time series. In his famous paper introducing the T^2 -statistic, Hotelling (1931) also introduced the idea of simultaneous tests and a confidence ellipsoid for the components of a multivariate normal mean.

The systematic development of multiple comparison methods and theory began later, in connection with the problem of comparing several normal means. The usual method had been the analysis-of-variance F -test, sometimes accompanied by t -tests at a stated significance level, α (usually 5 per cent), per comparison.

Fisher, in the 1935 edition of *The Design of Experiments*, pointed out the problem of inflation of error probabilities in such multiple t -tests and recommended the use of t -tests at a stated level α'

per experiment. Pearson and Chandra Sekar further discussed the problem (1936). Newman (1939), acting on an informal suggestion by Student, described a test for all differences based on tables of the Studentized range and furnished a table of approximate 5 per cent and 1 per cent points. Keuls formulated Newman's test more clearly much later (Keuls 1952).

Nair made two contributions in 1948, the one-sided test for slippage of means and a table for simultaneous F -tests in a 2^r factorial design. Also in the late 1940s, Duncan and Tukey experimented with various tests for normal means which were forerunners of the multiple comparison tests now associated with their names.

The standard methods for multiple comparisons of normal means were developed between 1952 and 1955 by Tukey, Scheffé, Dunnett, and Duncan. Tukey wrote a comprehensive volume on the subject which was widely circulated in duplicated form and extensively quoted but which has not been published (1953). The form of Tukey's method described in Section 3 for unequal n 's was given independently by Kurtz and by Kramer in 1956. Also in the early and middle 1950s, some multiple comparison methods for normal variances were published, by Hartley, David, Truax, Krishnaiah, and others. Cochran's slippage test for normal variances was published, for use as a substitute for Bartlett's test for homogeneity of variances, as early as 1941 (see Cochran 1941).

Selection and ranking procedures for means, variances, and proportions have been developed since 1953 by Bechhofer and others.

An easy, distribution-free slippage test was proposed by Mosteller in 1948—simply count the number of observations in the most extreme sample lying beyond the most extreme value of all the other samples and refer to a table by Mosteller and Tukey (1950). Other distribution-free multiple comparison methods—although some of them can be viewed as applications of S. N. Roy's work of 1953—did not begin to appear until after 1958.

The most important applications of the very general methodology developed by the school of Roy and Bose since 1953 have been *multivariate* multiple comparison tests and confidence regions. Such work by Roy, Bose, Gnanadesikan, Krishnaiah, Gabriel, and others is generally recognizable by the word "simultaneous" in the title—for example, SMANOVA, that is, simultaneous multivariate analysis of variance (see Miller 1966, chapter 5).

Another recent development is the appearance of some Bayesian techniques for multiple com-

parisons. These are discussed by Duncan in the May 1965 issue of *Technometrics*, an issue which is devoted to articles on multiple comparison methods and theory and reflects a cross section of current trends in this field.

PETER NEMENYI

BIBLIOGRAPHY

The only comprehensive source for the subject of multiple comparisons to date is Miller 1966. Multiple comparisons of normal means (and variances) are summarized by a number of authors, notably David 1962a and 1962b. Several textbooks on statistics—e.g., Winer 1962—also cover some of this ground. Many of the relevant tables, for normal means and variances, can also be found in David 1962a and 1962b; Vianelli 1959; and Pearson & Hartley 1954; these volumes also provide explanations of the derivation and use of the tables.

LINGUISTICS

- I. THE FIELD
- II. HISTORICAL LINGUISTICS
- III. THE SPEECH COMMUNITY

Dell Hymes
Yakov Malkiel
John J. Gumperz

I

THE FIELD

Linguistics has been called the science of language; but this definition begs the questions, What is scientific? What is language? Linguists themselves have not agreed; sometimes their answers have been quite narrow. If we are to consider the gamut of social science interests in language, we must adopt one of two approaches—either interpret “science of language” very broadly or conceive of it as part of some larger field.

In the first approach, “science” is taken in its broadest meaning, *Wissenschaft*, comprising all serious intellectual disciplines; “language” is taken as implicating all aspects of human speech. Linguistics is then truly the science of language, although as such it embraces work of both linguists and scholars in other disciplines. In the second approach, the “science of language” comprises only those kinds of knowledge for which linguists typically take responsibility. The science of language is then but part of a broader area of inquiry, the study of language; the science of language is linguistics proper, and the study of language may be called the field of linguistics.

The second approach is fairer to the present situation of linguistics. Linguistics is the indispensable basis for serious concern with any aspect of language, and its rapid growth is such that its effective scope may indeed come to equal the whole of the study of language. At present, the student of social science concerned with the place of language in human life must also consult other disciplines, perhaps including his own.

Our standpoint, then, will be that of the field of linguistics. We shall first sketch the development of linguistics within the context of the study of language, then characterize linguistics proper in terms of its scope and content today, and last discuss the import of its work with special reference to the social sciences.

Development of linguistics

The present expanding scope of linguistics is the outcome of a complex history. As a separately organized discipline, so named, linguistics is, however, quite young in English-speaking countries. The Linguistic Society of America was founded in 1924, and the Linguistics Association of Great Britain in 1965. Almost all of the independent departments of linguistics have appeared only since World War II. Indeed, “linguistics” has only recently displaced “philology” as a general name for the study of language, and “linguist” is still widely used by laymen for “polyglot” rather than for a member of a scientific discipline.

Early periods. Behind modern linguistics lies an accumulation of insight and knowledge that reaches to the early stages of human history. No known language is without at least some terms for facts of language and hence an elementary metalanguage of a protolinguistic sort. Such terms sometimes show close analysis of structural features; for the most part, however, the internal structures of language remain unconsciously known, and it is terms for uses and varieties of language that are elaborated. Every society indeed has terms, beliefs, attitudes, and knowledge concerning language that may be singled out as its *folk linguistics*. The character and extent of this folk linguistics are of interest as conditioning linguistic change and as part of the subject matter of ethnoscience. Where a separate discipline of linguistic study has emerged, the interaction between it and the folk linguistics of its society may also set some of the limits and directions of the discipline and hence interest the historian of science and the sociologist of knowledge. Some 2,500 years ago there began to appear disciplined studies of language that can be taken as heralding a stage of *national philologies*. In China,

India, and Greece, valued texts (the cultural arm, as it were, of expanding civilizations and aspiring states) came to be given special attention intended to preserve accurate knowledge of them and to aid in their use. These philologies were preceded by systems of writing, themselves embodiments of analysis of language. In the philologies, techniques of analysis became explicit, if with different emphases and differential success. The greatest achievement occurred in the Indian tradition (independently of writing), culminating in the work of Pāṇini (c. 500 B.C.). (Pāṇini was to influence the development of linguistics in Europe, once his work was made known there at the start of the nineteenth century.)

The Western study of language was shaped through most of its history by a tradition of philosophic thought and pedagogic grammars. In the classical world, analysis of language began amid controversies over the regularity or irregularity of language (*analogia* : *anomalia*), over language as part of nature or culture (*physis* : *nomos*), over relations between language and other subjects; and amid the establishment of Sophistic training and of educational institutions generally (see Robins 1951; Sandys 1903–1908; Marrou 1948). Etymological curiosity played a prominent part. A system of grammatical categories was evolved, based on the nature of Greek and then Latin. A great merit of the classical work was that it treated language structure integrally with language use; indeed, in education the grammarian was subordinate to the rhetor. Exclusive attention to the language (or languages) of an empire was a great limitation, shared by all early philologies. Given the social role of language study, this restriction was perhaps inevitable, but it was crippling to a general knowledge of language itself.

Early modern period. In the medieval period of the West (during the intermittent periods of renaissance before that which bears the capitalized name) theoretical notions about the rational structure of language were elaborated and language's place in education and human life discussed (see Bolgar 1954; Robins 1951).

Skills that had begun in the classical world in the first renaissance of Greek literature—that of Alexandria—reached new heights in the Renaissance proper, and the tradition of classical philology which it founded provided the model for textual analysis and criticism in all fields, as well as models for grammars and dictionaries of the emerging national philologies in Europe. As the literary use and serious study of modern European languages grew, an empirical knowledge of lan-

guages from Asia, Africa, Oceania, and the New World slowly began to accumulate, especially through the field work of missionaries, history's first organized body of ethnographers. By the eighteenth century the growing body of information was considerable, and there were scientific expeditions whose mission included collection of linguistic data (see Gray 1939; Wonderly & Nida 1963).

Some criteria of relationship among languages had been sought earlier in attempts to harmonize the three great cultural languages (Hebrew, Greek, Latin) and to establish the origin of the peoples of the New World, as well as of modern European peoples. The search for relationships was abetted no doubt by the Biblical account of Babel, which (1) asserted original unity of all languages, and (2) left the details of differentiation open to discovery (see Borst 1957–1963; Metcalf 1964).

In this period the theoretical unity of human language was treated in the Cartesian rationalism of Leibniz and others, in British empiricism, Scottish "common sense," and French materialism. Indeed, as the intellectual foundations for the social sciences developed, the nature of language, posed as a problem of its origin in history and in the individual, engaged most major theorists—Hobbes, Locke, Rousseau, Adam Smith, Condillac, Herder, etc.—bearing as it did on the fundamental nature of man and the relationship between the natural and cultural worlds.

It is conventional to date the history of linguistics proper from the recognition of Sanskrit and the rise of diachronic linguistics, especially Indo-European studies, in the late eighteenth century and early nineteenth. This view (indeed, origin myth) preserves too much of the self-consciousness of an intellectual climate (romanticism, historicism) set off against the image of its predecessor, the Enlightenment. There was justice in the self-consciousness: in the study of language works were produced that became models and starting points for subsequent scholarship; with specialization, chairs, scholarly organizations, and journals increased quite dramatically. It is almost impossible, however, to fix any one point between the mid-eighteenth century and the mid-nineteenth century as decisive intellectually for the development of the successful methods of Indo-European study; Turgot, Rask, Bopp, Grimm, and Schleicher each has his claim to a contribution. Regarding theoretical views, some would now set aside much of the nineteenth-century effort, emphasizing the preceding rationalist inquiry as a more relevant predecessor. The work of Wilhelm

von Humboldt thus comes to seem both an end point to developments of interest in the seventeenth and eighteenth centuries and a starting point for a strain of general linguistics in the nineteenth century.

No doubt the salience of periods of past linguistics will continue to change as modern linguistics changes. If we are to understand the history of linguistics, not for partisanship, but as a case in the comparative study of the general history of science and scholarship, one point is essential. Linguistic research, like social science research, proliferated as a sustained, organized, autonomous activity in the nineteenth century, but from an intellectual and empirical base in the general rise of scholarship and science in Europe as part of the expansion, at once intellectual and commercial, of its known world. With that rise began what can be truly called *general linguistics*, a linguistics which, while interdependent with the continued development of philologies and of specializations of other sorts, came to take as its compass all the languages of man. (On the place of linguistic thought in intellectual history, especially the place of language in human nature and culture, see Verburg 1952; Chomsky 1966; Cassirer 1923, chapter 1.)

Nineteenth century. The major study on nineteenth-century linguistics (actually a period approximately from the French Revolution to World War I) records it as the triumph of historical work, especially of comparative Indo-European (Pedersen 1924). From that standpoint the course of the century is one of increasing precision and power of historical method and of its very wide application. Indo-European studies held the center of the stage, partly because of their institutionalization in Prussia and subsequently elsewhere and partly because of the accident of cultural history that the languages prospective Indo-European specialists had to learn in school were the classical "languages of culture," Greek and Latin, together with their native languages and perhaps some other European language, gave these students intimacy with three or four branches of the language family they were to reconstruct. This cultural support and internal availability of data were not duplicated elsewhere. The Hungarian, Gyarmathai, had had the methodological insight to relate Hungarian and Finnish, in 1799 (see Pedersen [1924] 1962, pp. 105-106), but the languages of the family (Finn-Ugric) to which Hungarian belongs were scattered in Russia and the north, and scholars had to rely on cumulative field work. Moreover, there was no prestige in working out the relationship of one's mother tongue to the languages of poor "fish

eaters" (the heroic Turkish conquerors were more attractive as linguistic kin, thus leading much research into a blind alley). Indo-European scholars worked amid the rise of Oriental philology and of interest in the "wisdom from the East" symbolized by Sanskrit.

Among the main accomplishments of the period were the pioneering comparisons of Rask (who was not adequately recognized in his own day); the comparative grammar of Bopp; the recognition of regular patterns of sound change in Germanic by Grimm (and Rask); the etymological dictionaries of Pott and Fick; the method of reconstruction and the family-tree model (*Stammbaum*) of relationship of Schleicher; the more exact specification of regularities in change in sound and of the role of grammatical analogy of the *Junggrammatiker* and others of the 1870s (Ascoli, Verner, de Saussure, Brugmann); the wave model of relationship (*Wellentheorie*) of Schmidt, complementing that of the family tree. The first basis was laid for the historical study of many language families, both within and outside Indo-European (e.g., comparative grammars of Romance, Celtic, Dravidian, Bantu, Athapaskan). Near the end of the period, the great comparativist Meillet, while calling for attention to regularities independent of specific histories, could rightfully state that the principles already developed for the handling of regular sound change, analogy, and borrowing could continue to be fruitfully extended to all the language families of the world.

The traditions of anthropological philology also became established in this period, beginning perhaps with Herder's thesis of the individuality and the scientific and humanistic value of the language and literature of every people, whatever its stage of development. This attitude was to be freshly stated many times, for example, by Boas, a century later. Much anthropological study of language has indeed been the philology of peoples without philology of their own. In this sense anthropology has been the third of the great philological enterprises of European civilization, following upon and complementing classical and Oriental philology.

A master term for the study of language was *philology*, a putative "queen of the sciences" to some, although "linguistics," *linguistique*, and *Sprachwissenschaft* also were in use. Historical linguistics, requiring interpretation of texts, was often termed "comparative philology" in English-speaking countries; and since philologists proper produced the needed grammars and dictionaries, descriptive work also was often identified as "philology." Analogous to "classical philology," the

study of contemporary European languages was labeled part of "modern philology" (*Neuphilologie*), and study of a particular set would be, e.g., not "Romance linguistics," but "Romance philology." In American anthropology, "philology" remained the common term into this century (e.g., Boas was retained by the Bureau of American Ethnology as "philologist"). In British usage and some learned American usage "philology" continued to serve until very recently. After World War I the trend among practitioners themselves to distinguish sharply between "philology" and "linguistics" was well established, however favorably the relationship between the two might be viewed (Pedersen [1924] 1962, p. 79). Philology might range far, but it remained inseparable from the study of texts and history, and linguistics was being defined as a more general study of language.

Looking back from the standpoint of contemporary linguistics, one sees in the nineteenth century important strands, which were largely neglected in accounts of the triumph of historical work. One is well known and the progenitor of continuing lines of work—linguistic geography and dialectology. It emerged in a rising wave of interest in geographical distributions in all the human sciences during the half-century embracing the turn of the twentieth century as midpoint. [See LINGUISTICS, article on THE SPEECH COMMUNITY.]

A second major trend in general linguistics stemmed from von Humboldt and others and sought cognitive import in an evolutionary typology of languages. Carried on by Schleicher, Steinthal, and others in various forms, the effort was later discarded amid a general rejection of evolutionary sequences of stages in the cultural sciences. The whole-language labels, such as isolating, agglutinating, inflectional, polysynthetic, and incorporating, were retained only for individual traits that might be compresent within one language.

The concern with typology was the main source of the attention paid to the structural cut of languages and to its possible import (witness the joint launching of the first journal in social psychology by Steinthal and Lazarus in 1860); and the cognitive interest was retained, but associated with grammatical categories and processes of individual languages, quite divorced from broad classes and stages. (Through Boas the interest became an intrinsic part of American linguistic anthropology.)

Typology was thus part of a third trend, the preparation in the nineteenth century of the structural outlook that was to dominate the twentieth.

In this outlook much was to depend on the approach taken to the sounds of speech. In the nineteenth century European languages often were taken as a norm, such that the sounds of "primitive" languages seemed odd and even to lack constant units—as so often, projection of a lack of structure here betrayed an inadequate understanding of the nature of the primitive language being studied. Speech sounds were studied officially by a phonetics conceived as a natural science (*Naturwissenschaft*), not as a part of linguistics. Seeking universal objectivity through finer physical observation, phonetics plumbed a pit of variation, failing to see that universal invariants in language can be attained only through recognition of a patterning within language itself, and that within a language, objectivity of units is in the first instance intersubjective and qualitative. In the 1880s such a cultural (or psychological) approach to speech sounds was worked out in Kazan by Baudouin de Courtenay and Kruszewski and was independently adumbrated by Boas. Their insights became effective only later—that of the Kazan school in the work of de Saussure, Trubetskoi, and Jakobson, the Boasian heritage in Sapir's great paper, "Sound Patterns in Language" (1925). Meanwhile, the comparativists, by establishing ever more precisely the principle of invariance in historical reconstruction, anticipated and aided application of this principle in nonhistorical contexts. De Saussure's brilliant reconstruction of a part of the proto-Indo-European vowel system, for example, was not only confirmed a generation later by the discovery in Hittite of a phonological feature postulated purely on internal evidence in the reconstruction, but its treatment of relationships within and between languages as manifestations of an underlying invariant feature earlier in time is also quite the same in form as the treatment of variants within a language as manifestations of an underlying invariant compresent in time, i.e., as manifestations not of an origin but of a present system.

Twentieth century. Modern synchronic, structural linguistics emerged essentially after World War I. Despite the groundwork that had preceded it, the participants in its emergence saw not continuity but conflict. De Saussure viewed synchronic and diachronic study as antithetical—the one dealing in systems, the other in atomistic traits; and many subsequent structuralists rejected historical work, at least as practiced. At the same time, many historical scholars rejected the new descriptive approaches. Even in American linguistics, where both history and structure have often been of com-

mon concern, as the work of Sapir and Bloomfield shows, the issue has been debated (Hockett 1948, p. 188; Hymes 1964a, p. 600). In some circles, especially in Europe, conflict over this issue is perhaps only ending now.

The new movement was part of a general upheaval of intellectual interests after World War I and of the general shift from a primarily historical perspective to an interest in structure and form. With it came the definite triumph of "linguistics" as the general name for the study of language and the development of several different orientations toward the proper tasks of linguistics, often enough excluding portions of the general study of language by way of self-definition.

The first text of structural linguistics, the posthumous *Cours de linguistique générale*, published from lecture notes by students of de Saussure, ends with the maxim that linguistics has for its true and only object language itself (i.e., not facts of history, psychology, sociology, or whatever). De Saussure introduced the distinction *la langue* : *la parole*. It subsumes a variety of contrasts and has been variously interpreted and used, but the main import has been that the linguist's task is the study of *la langue*, the underlying system and social fact (de Saussure was influenced by Durkheim, as was Meillet), rather than the various aspects of speech and other uses of language that were understood as *la parole*.

Saussurean linguistics as such was maintained in Switzerland by Sechehaye, Frei, Godel, and others. In Denmark Hjelmslev drew inspiration from de Saussure (and also from Sapir) and developed with Uldall a methodological algebra, *glossematics*, which postulated the immanence of language and made no assumption as to its empirical reality. In Czechoslovakia two Russian scholars, Trubetskoi and Jakobson, collaborated to lead in the development of a structural outlook uniting synchronic and diachronic work and giving attention both to internal and external functions of language. The accomplishments included a distinctive methodology for phonological and grammatical analysis; basic examination of phonological typology in connection with a search for general laws; new emphasis on the diffusion of linguistic features, structurally interpreted; and analyses of social and poetic varieties of language. In England J. R. Firth advocated a flexible, encompassing descriptive approach, one shaped partly by the English tradition of phonetic research and partly by Malinowski's notion of the "context of situation."

In the United States the matrix of structural

linguistics was in large part anthropological. Boas had prepared the way by his critique of existing generalizations about the nature of language in the light of American Indian evidence and by his insistence on the description of each language *sui generis*. (The major statement of his contribution is the 1911 introduction to the *Handbook of American Indian Languages*.) His student, Sapir, put field work with a multitude of Amerindian language structures to brilliant account in his *Language* (1921) and in his 1925 study established the basic principle of structural analysis for both American linguistics and ethnography. Around Sapir and Bloomfield gathered the subsequent leaders of professional linguistics. In the United States Bloomfield's *Language* (1933) was the first systematic exposition of the new descriptive approach, and it became the standard reference for a generation. Both Sapir and Bloomfield stressed the autonomy of language and linguistics. Sapir's *Language* is a masterful set of variations on the theme of the autonomy of grammatical form, and Bloomfield's book declares that the study of language has many times been approached, but never properly begun, because of failure to focus on language in its own right. Granting this autonomy, both saw larger implications for the results of linguistics, and indeed an interdependence with other disciplines—especially Sapir; in this respect, Bloomfield remained the more austere.

Each of these strands of structuralism has been labeled—the Geneva school, the Copenhagen school, the Prague school, the London school, the Yale school (although the differences between Sapir and his successor Bloomfield perhaps require recognition of two Yale schools). It must be remembered that distinguished linguists worked in the Netherlands, France, and elsewhere, without acquiring separate names and images, and that the labels are poor predictors of the work of individual scholars in the places named. The labels do serve as markers of salient intellectual emphases and outlooks. Differing intellectual contexts and assumptions led to sometimes acerbic exchanges in the first years after World War II; in particular, the stringent behaviorism dominant in the United States was set in method and attitude against the more open-minded empiricism found in Britain and against those influenced by phenomenology, logic, and dialectic on the Continent. There was salient skepticism, if not outright rejection, of the study of meaning, and there was antipathy to statements in terms of process in the Neo-Bloomfieldian camp. In the United States, the effective scope of linguis-

tics became especially narrow for a time (see Joos 1957), in contrast to European outlooks and, indeed, the outlook of Boas and Sapir.

Recent trends and structural models

Developments within structural linguistics continue to hold the center of the stage. The main trend has been away from primary concern with phonology (whose conquest by structural methods was a main achievement of the 1920s and 1930s and in terms of which the battles of the day were fought) to concern with morphology, syntax, semantics, and, to some extent, stylistics, or poetics. In the 1940s and early 1950s great attention was given to the analysis of grammar in terms of morphology, the identification and distribution of forms. Especially in the United States there was an attempt to analyze grammar in terms analogous to those used in phonology, and insofar as possible, on the basis of the results of phonological analysis. This strategy of working upward from phonology fitted an emphasis on overt data (rather a "decoding" one) and a reluctance to deal with imputed entities. In the words of Joos, the maxim was "text signals its own structure." European scholars had usually taken the psychological reality of linguistic structure into account, as had Boas and Sapir; and glossematics began with the higher levels of text and grammar, working downward to phonology. In the late 1950s and the 1960s Noam Chomsky has stressed the centrality of grammar and the underlying mental abilities of users of language. His central point has been that structure in text is largely recognized not because overt signals are perceived but because users of a language apply their knowledge of grammatical structure. Chomsky's work, along with a general revival of interest in semantic work, has been the major force in bringing general American opinion into agreement to this extent with European and earlier American interests.

Models of language structure current on the American scene can be noted cursorily as follows:

(1) The Trager-Smith-Joos model, dominant in the early 1950s, treats phonology, grammar, and semology as coordinate and parallel in organization. Relations of language to culture and society are treated as questions of "metalinguistics." Language is associated with other communicative systems, such as *kinesics* (gesture and body motion) and *paralinguistics* (nonlinguistic phenomena of voice), within a general framework for the analysis of culture (Hall 1959).

(2) The *tagmemic* model, devised by Pike and subsequently developed by Longacre and others, has become the framework for descriptions from many

different parts of the world, used especially by the members of the Summer Institute of Linguistics (a group devoted to translating the Bible). It treats phonology, grammar, and lexicon as coordinate hierarchies, parallel in organization. The concept of *tagmeme* treats as central the relation in grammar between a position and the class of elements that can occur in it, thus reintroducing and generalizing the notion of paradigm. Inspired by Sapir, Pike has sought to generalize linguistic methodology to make it applicable to cultural behavior (see Pike 1954). In doing so he has coined the terms "emic" and "etic" (from "phonemic" and "phonetic") for the difference between classifications of phenomena that are based on features validated internally in terms of the structure in question and classifications that are based on externally devised or generalized criteria.

Recent descriptive work done by Pike has emphasized use of matrices; by Longacre, analysis of strings and inclusion of transformations (1964).

(3) The "means-ends" model, as Jakobson (1963) has dubbed the original Prague school approach, has diffused into several lines of American research, largely through Jakobson's presence since the early 1940s. There is widespread acceptance of the notion and importance of distinctive features in phonology: the "letter size" units, or phonemes, are not ultimate constituents but bundles of contrasting components (e.g., voicing, produced by vibration of the vocal chords, versus voicelessness, or absence of vibration, which distinguishes the otherwise identical series of English stops /p t k/ : /b d g/). But not all linguists follow Jakobson in defining phonological features acoustically (in terms of the physical properties of the speech signal), some retaining definition in terms of articulation (where and how the sounds are produced); neither do all linguists follow him in supposing a proposed set of 12 phonological features to be adequate for describing all languages or in regarding distinctive features as always forming oppositions of a binary sort. Jakobson's analyses of grammatical categories in terms of distinctive semantic features have helped shape componential analysis; his work has influenced literary scholarship, ethnography, and psychology as well. [See COMPONENTIAL ANALYSIS.]

An enduring importance of the Prague school is that it always keeps the true social complexity of language in view as an object of linguistic study. In its conception a language is a dynamic "system of systems." A language is never a static, homogeneous system, but a developing set of interdependent, imperfectly adjusted subsystems, some of

whose items are disappearing, some emerging. A language, moreover, is a set of means specialized to a multiplicity of communicative and social ends; for example, there are referential, expressive, and directive functions in speech; and literary, standard, and other varieties of a language. (On the history and present development of the Prague school, see Vachek 1964; 1966a; 1966b.)

(4) The most influential model both in the United States and abroad is that of *transformational-generative grammar*. As first formulated in the early 1950s by Zellig Harris (codifier of much post-war American method), transformations were a technique for syntax and text analysis serving to account for relations between sentences. Particularly telling have been the ways in which transformational analyses can account for the ambiguity of a sentence in terms of its derivation from two different underlying sentences; uncover an underlying difference between two superficially quite similar sentences; and integrate the productive systematic relations between different forms of sentence (e.g., actives, passives, negatives).

In the work of Harris' student, Chomsky, transformations have become part of a new model of language as a whole and of a program for radical recasting of previously held assumptions and goals. Analysis of the underlying "deep structure" of grammar is stressed; much of what was treated by earlier descriptive linguistics is relegated to "surface structure." Grammar shapes phonology rather than the reverse, and the phonological output of a grammar is specified in terms of distinctive features. (For the first influential monograph, see Chomsky 1957; for subsequent views, see Chomsky 1964; 1965; 1966.) The program is one of attack on behaviorist and positivist outlooks from a standpoint of rationalism and recent philosophy of science. The Neo-Bloomfieldian goal of an algorithm, a mechanical procedure for the analysis of a language, is shown to be futile, and earlier models of syntax are found inadequate to account for the actual facts of languages and the abilities that users of languages must have. Indeed, the goal of accounting for observed data is defined as mere *observational adequacy* (in effect, merely reporting the data). At the least, linguistics must aim for *descriptive adequacy*, an account of the knowledge that a fluent user of a language has of its structure, and which he or she can apply in producing and interpreting the infinite set of sentences of which a language is normally capable. What is crucial is the agreement of a grammar not with a corpus but with users' judgments of acceptable and unacceptable sentences. The true goal of linguistics

should be *explanatory adequacy*; that is, linguistics should characterize the nature of the equipment by means of which a child acquires such knowledge. To achieve the normal yet nearly miraculous result of an infinite capacity from a finite experience in but a few years, a child must be presumed to apply actively a native endowment, formulating theories to account for and go beyond the speech he hears. The rapidity and accuracy of a child's success, no matter what the language, indicate that all languages are of only one or a few fundamental types and that the contribution of the native endowment must be great. In this light the earlier emphasis in American linguistics on the diversity of languages is reversed in favor of an active search for universals.

The focus of linguistic theory is thus reformulated as *linguistic competence*, the knowledge of the ideally fluent user of language in an ideally homogeneous speech community. Theory is completed by an account of *linguistic performance*, comprising the various conditions—psychological, occasional, social—that modify and affect the expression of underlying competence. The critique of learning theory and behaviorism provides a new program for psychologists; the model of language stimulates new work in semantics and to some extent in stylistics and ethnography, although some lines of research into the social role of language are considered misguided or premature. It is fair to say that transformational-generative grammar has replaced Neo-Bloomfieldian work as the focus of attention today. Apart from the close-knit group centered about Chomsky and Halle, some linguists join transformational syntax with other approaches, especially in phonology; and some transformationalists abjure Chomsky's views of the psychological and philosophical import of the model (e.g., Harris, Henry Hiz).

(5) The *stratificational* model owes its name and central formulation to Sydney Lamb. It has attracted several leading linguists (e.g., Hockett, Gleason) and has affinities with the work of Halliday. Originating as a systematic explication of principles in earlier American descriptive work and as a response to needs in computer use, especially mechanical translation, the model treats language as four levels, or strata—semology, lexology, morphology, phonology. The elements of the several strata are related by realization rules, which may be traced either in speaking (semology to semology) or in hearing (phonology to semology). The model thus is intended to represent the processes of a user of language in either activity (see Gleason 1964 and Lamb 1966 for other formalizations). As

with tagmemic analysis and the Harris-Hiz type of transformational analysis, there is interest in units larger than the sentence, such as whole narratives. The sememic analysis has close ties with work in componential analysis and ethno-science.

(6) *System-structure* is a generic name for models derived from the Firthian heritage in Great Britain. The most notable of these models is what has come to be known as the "scale-and-category" grammar of M. A. K. Halliday and others (see Halliday et al. 1964; McIntosh & Halliday 1966). A special interest of the approach is its direct incorporation of questions of "institutional linguistics" (sociology of language) and its varied application to problems of language teaching, translation, analysis of style, and study of social dialect.

While models of the way grammars should best be written are the center of attention, other lines of linguistic work continue to develop, often revitalized in the light of structural principles; new interests emerge, often as applications and extensions of structural perspective; the concerns of the humanities and social sciences and of social institutions entail selective attention to the results and possible applications of linguistics. In short, controversy focused on structural models should not obscure the great variety of present-day linguistic activity. This variety can be grasped if one considers the three main ways, each cross-cutting the others, in which linguists may be grouped for purposes of congresses, journals, appointments, and so forth. There is affiliation with one or another of the structural approaches (some scholars affiliate with none); there are the subdisciplines, such as the phonetic sciences, lexicography, semantics, stylistics and poetics, onomastics, philology, dialectology, formal and mathematical linguistics, applied linguistics, anthropological linguistics, psycholinguistics, and sociolinguistics; and there are the groupings in terms of languages studied, whether in the sense of language family (Indo-European, Germanic, Algonquian linguistics) or area (African, Indian, Oceanic linguistics).

Distinctive constellations of approach, subdiscipline, and languages studied do occur, coupled with nationality or geographical region; but the overriding trends today are an internationalization and diffusion of interests and outlooks and a broadening and integration of them. Each major structural school, for example, has adherents in several countries, and a variety of links with subdisciplines and language families and areas. Moreover, each structural school has had a conception of structural linguistics as contributing to a larger enterprise, such as a general science of signs (semi-

ology, or semiotics), and as a link in the integration of the natural and social sciences, or at least as a strategic sector of social science; and such contributions are increasingly being realized.

Like many histories, this of linguistics has been rather Hegelian, moving from place to place and topic to topic as the "spirit" of the main advances moved. The main outlines might be caricatured in a Hegelian manner, describing the successive stages as "no language is known" (folk linguistics); "one language is known" (early national philology); "few languages are known" (later philology); and "many languages are known" (general linguistics). Yet any period comprises both the new and emerging and the old and steadily continuing, in a variety of forms, as has been indicated for the present state of linguistics. The nineteenth century was not all historical; the twentieth century is not all structural grammar; and if future linguistics builds on both in pursuit of a dominant functional concern with the place of language in human life, it will be in a spirit not of disregard of other concerns but of their integration. (On current trends, see Mohrmann et al. 1962; International Congress . . . 1963; Ivić 1965; *Current Trends in Linguistics; Biennial Review of Anthropology*.)

Content of linguistics

We must now take stock more exactly of the present content of linguistics. Linguistics proper can be defined by tasks that remain constant and characteristic. These central tasks are to describe languages, to classify them, and to explain their differences and similarities.

Descriptions of linguistic data. The descriptive task (understood as equivalent to analysis) is primary. In pursuing it, linguists may use a variety of means for determining data and may place data in a variety of frames of reference. To grasp this variety a general framework is needed. We shall adapt and enlarge one put forward by Hockett (1948, pp. 188-190; Hymes 1964a, pp. 600-601), distinguishing four kinds of means by which data are determined (contact, philological, reconstructive, theoretical) and four major frames of reference within which data are placed (syn-

Table 1 — Means and frames of reference for linguistic data

FRAMES OF REFERENCE	MEANS			
	Contact	Philological	Reconstructive	Theoretical

chronic, diachronic, diatopic, synchronic; Table 1 outlines this descriptive mode.

Means for determining linguistic data. Of the four kinds of means, *contact* subsumes first-hand observation, interviews, surveys, and experimentation in direct contact with users of a language—in short, the various forms of field work and laboratory work, including introspection into one's own speech habits. Such work has been most characteristic of descriptive linguistics and dialectology, and of anthropology, but the expanding role of psychologists and sociologists in the study of language must be noted (see Lounsbury 1953; Hymes 1959; Samarin 1967; Berko & Brown 1960; Ervin-Tripp 1964).

The *philological* methods are those used in the interpretation of the nature and transmission of written records, especially texts. Such methods are not limited to the study of classical languages or the languages of civilizations with writing. In the narrower sense that philological methods have come to have for some linguists, a field worker may find himself later in a philological relationship to his own materials; and in areas such as the New World the interpretation of records left by earlier investigators is indispensable for many languages no longer spoken. In the broader, earlier sense of philology, the method leads on into the general interpretation of texts for their cultural content as well as their linguistic form (see Sandys [1903–1908] 1958, vol. 1, pp. 4–13; Bernardini & Righi 1947; Hymes 1965; Malkiel 1966).

By *reconstructive* methods are meant those methods that use systematic variation in known languages (or dialects) to infer the presence and perhaps the patterning of features unknown in some other. When the evidence is from one language (or dialect) and the inference is to an earlier stage of it, the work is known as *internal reconstruction*. When the evidence is from two or more dialects or languages and the inference is to an earlier ancestral language, one usually speaks of the *comparative method*. Notice that in linguistics the term "comparative method" has this specialized use. Scholars in other fields have sometimes been misled into taking it as designating a general method of comparison, or as equivalent to such other techniques as the method of controlled comparison in social anthropology or the comparative method of nineteenth-century social evolution. Analogues to these in the study of language fall within the synchronic frame of reference and are quite distinct from what linguists speak of as the "comparative method" (see Bloomfield 1933; Hoenigswald 1960).

A less common form is that in which the infer-

ence is from a series of geographically linked languages or dialects to an intermediate or adjacent one; such use may count as a sort of reconstruction in space rather than time.

Theoretical methods concern aspects of data that are postulated by a general theory or inferred on theoretical grounds. A theoretical component is present in any description, although the extent to which it is recognized, if at all, may vary. Some examples are: that dialects be described in terms of the elements of a fixed over-all pattern; that distinctive features be binary; that rules specifying the phonological shapes of words be ordered (or unordered); that of two differing accounts the shorter is to be accepted; that of two differing accounts the more intuitively persuasive is to be accepted; and so forth.

Frames of reference. As frames of reference, linguists commonly distinguish "structural," "descriptive," or "synchronic" from "historical," or "diachronic," linguistics; linguistic geography, or dialectology, and typological comparison, together with general linguistics, often are distinguished as well. The implicit logic is to separate the primary description of languages from concern with change (through time) and with variation (in space), and from contrast and generalization independently of space and time. In adopting this scheme (somewhat relabeled for symmetry's sake), we recognize that no concise grouping can be wholly satisfactory and that the names must be somewhat arbitrary, designating as they do gross clusters of work that overlap and are internally diverse.

Synchronic description treats features (dialects, a language) with respect to a particular time, and, by implication, with respect also to a particular place. ("Structural" is used as a surrogate, but descriptions of the sort intended developed long before modern structuralism, and analysis within any frame of reference may be methodologically structural.) While other kinds of work may be strictly speaking "synchronic," the common connotation of the term in linguistics is that for the purpose at hand, data can be treated as coming from a single source and as essentially homogeneous or unified; in effect, "synchronic" means an idealized single case. The classical presentation of such a synchronic analysis is in the form of a grammar, texts, and dictionary. (For treatments of grammatical description, see Harris 1951; Hockett 1958; Gleason 1955; Bach 1964; Katz & Postal 1964; Longacre 1964; Martinet 1960; Robins 1964; Chomsky 1965; McIntosh & Halliday 1966; and the several approaches represented in the *Monograph Series on Languages and Linguistics* [see "Report

of the Fifteenth Annual . . ." 1964] and the journal *Language*. On texts, see references in Hymes 1964a, p. 365; on dictionaries, p. 209.)

A synchronic structural description must choose or assume a particular norm—say, the standard speech of educated persons or the informal patois of lifelong inhabitants of a village. That is, any serious description must specify its boundary conditions—for whom and when and where it holds. Questions of contexts, purposes, and modes of use must enter (a point most consistently made by Firth and other British linguists such as Robins 1964; Halliday et al. 1964; Dixon 1965). Such questions are often distinguished as "functional," "structural" serving for the internal make-up of language. This usage, with its internal-external dichotomy, is not happy, however, since use must itself be structurally analyzed and since the point of structural analysis of the make-up of language is to treat features in terms of their functional relationships (e.g., sounds in terms of the contrasts into which they enter to distinguish utterances; see Sapir 1925). Considerations of structure and function apply throughout linguistics, and the extension of this joint scope is of special importance to the social sciences. It is better to specify the exact kind of structure and function in question, rather than to rely on a usage that implies a false discontinuity.

What the classical presentation of a description of use might be like is not yet known. Models for the description of language use have been often postulated, but actual analyses are rare. As prolegomena to such descriptions one can cite the framework employed by Halliday (Halliday et al. 1964) and the concept of an "ethnography of speaking" (Hymes 1962; 1964b). Restricting attention here to an idealized single case, one can say that an ethnography of speaking would identify and describe the speech events and sequences of speech acts recognized in a community and their distribution; their purposes and interactional norms (e.g., formal/informal); the relationships within speech events—who can participate as speakers and hearers, with regard to what settings, topics, message forms, channels, and codes; the patterning of messages in exchanges and sequences (conversations, curses, narrations, etc.); the hierarchies of functions (referential, expressive, rhetorical, poetic, and other) in such events; and the role of language with respect to other codes. No full accounts yet exist.

Diachronic description treats features (dialects, languages) in terms of time. Often one is con-

cerned with changes in a single line of development, but features that remain stable may be of interest too; and the tracing of borrowings and their etymologies into earlier periods of other languages may become an objective of study. Among products of diachronic description are historical grammars, etymological dictionaries, statements of sound laws connecting stages of languages (e.g., Grimm's law), depictions of innovations leading to the present vocabularies of members of language groups, and so forth. Diachronic descriptions need not draw a hard line between so-called internal and external aspects of language change, and, indeed, for many purposes cannot do so. Beyond the question of what has occurred, questions of when, where, how, and why arise, requiring reference to uses, contexts, and values for their answers. It is not unusual, however, for a distinction to be drawn between *historical linguistics*, internal change, and *language history*, external events. (See chapters on language change in Sapir 1921; Bloomfield 1933; Hockett 1958; Gleason 1955; Martinet 1960; 1962; Hymes 1964a, parts 8 and 9.)

Diatopic description treats features (dialects, languages) in terms of space; it is thus inseparably associated with dialectology. Two observations must be made. First, dialectology is often synchronic description; important early work in Europe, for example, was motivated by concern for local forms of speech as against standard languages. There is also a European tradition of local ethnography that includes community speech as well as objects and practices. Second, diatopic description proper has not usually been undertaken for its own sake. Interest in the distribution of phenomena has often derived from diachronic questions of origin, spread, and loss. For dialects and languages, one may seek to infer an earlier location, migration, dispersion, or particular processes of formation. For features, one may seek to infer a particular history and also to sharpen a theory of linguistic change.

It remains that dialectology and linguistic geography require separate recognition, both analytically and for their special traditions of work. Earlier diatopic work most familiarly focused on sounds and words and produced atlases and maps. Recently there has been much recasting of earlier work in structural terms—e.g., analyzing the distribution of sounds in terms of phonological patterns (Hymes 1964a, p. 481).

A second kind of diatopic description is concerned not with geographic space but with social space. Earlier work was most concerned with the social dimension as it "horizontally" tied together

several communities. Current work stresses "vertical" relations within communities, talking more of *social dialect* than of geographical dialect.

Such study may focus on the distribution of specific linguistic variables within a community; in doing so it gives special attention to the social valuation and role of these variables, for the light shed on the community as well as on processes of origin and diffusion (see Fischer 1958; Labov 1963; 1964). Description of variation in social space may also focus on all the varieties of speech to be found in a community—speech levels, men's speech and women's, baby talk, argots, and the like. The features of such forms of speech are specifiable structurally, but they appear here as aspects of the use of language within a universe that is defined first of all in social, not linguistic, terms. From an internal linguistic standpoint, cases of, say, men's versus women's speech appear only when the differences intrude into the normal description of a language, e.g., as constant differences in the phonological shape of lexical items or as obligatory alternates for inflectional elements. The speech appropriate to men and women presumably is differentiated in every society, however; it should be possible to describe how to "talk like a man" and "talk like a woman" everywhere. From the present standpoint one would inquire into the nature of the differentiation—whether or not it could be ignored in an ordinary grammar.

Such diatopic work is closely linked with description of use within a community. Indeed, in the description of a single community a full diatopic account and a synchronic ethnography of speaking differ only by an element of definition. An idealized synchronic account would restrict itself to a single variety of a language; but in fact every speech community has at least three (formal, conversational, slang). At the level of relations among a series of communities, however, or of relationships within a unit such as the nation, new complexities and types of problems emerge, so that the community-linked perspective of an ethnography of speaking can be considered part of a more general enterprise, the construction of an integrated theory of sociolinguistic description for social units of whatever scale and size.

Syncretic description compares dialects, languages, or features without regard to relative position in space and time. Such work is often called "typological," especially when the purpose is structural classification of whole languages or their subsystems. "Comparative" would be a natural term, had it not been pre-empted for a reconstruc-

tive method and, by extension, the particular kind of work to which that method contributes. Some British linguists indeed seek to recapture "comparative" for comparison of languages generally, including comparison for purposes of translation and language teaching (often called "contrastive linguistics" in the United States; see Halliday et al. 1964, pp. 111–112). *Syncretic* (from the Greek *synkrisis*, meaning "comparison") seems useful as a term that is both general and unambiguous, and so we introduce it here.

Syncretic description is undertaken sometimes simply to exhibit what diversity of structure may exist among languages, perhaps also to devise a classificatory scheme or measures for a scheme. Two particular purposes can be distinguished as *contrastive* and *generic*. A contrastive study sets out to specify differences, as in the characterizations of French and German by Bally or in the setting of Hopi against "Standard Average European" done by Whorf. (Whorf introduced the term "contrastive" in this use.) A generic study seeks significant commonalities in order to establish universals of language—underlying principles either true of all languages or so widely true independently of relationship in time and space as to require a general, rather than a historical, explanation (see Conference on Language Universals 1963; Martinet 1962; Chomsky 1965; references in Hymes 1964a, p. 661).

Syncretic description of uses and contexts also has contrastive and generic purposes, the contrastive being more salient. A notable example is Bernstein's model of two types of code, elaborated and restricted, which are characterized by differences that include the signaling of subjective intent in verbally explicit form versus its transmission extraverbally; the focusing of attention on verbal versus extraverbal channels; reliance on verbal persuasion versus authority; orientation toward personal discretion within roles versus status relationships and shared assumptions. The model has been most discussed with regard to class differences in England and the United States, but it has a more general application. For members of any class some situations may call for restricted code behavior; and it seems likely that aspects of socialization pertaining to whole societies can be contrasted in these terms. Other examples of syncretic work of this sort contrast types of verbal interaction as transactional or personal; types of bilingualism as coordinate or compound; types of speech situation as formal or informal; and the like. (These examples and related ones are discussed in articles by Bernstein,

Ervin-Tripp, and Gumperz in Gumperz & Hymes 1964, and in articles by Bloomfield, Gumperz, Ferguson, Diebold, and Garvin in Hymes 1964a.)

Each of the contrastive analyses might be directed toward generic purposes. Thus one might have a systematic comparison of baby talk or of men's and women's speech with a view to generalizations as to their places in human society as a whole. A further step would be to analyze and compare ranges and uses for whole languages or speech communities, seeking to identify recurrent patterns of function (independent of historical connection) and to integrate such patterns with the results of the contrastive typologies. Such an approach entails a consideration of the place of language among other modes of human communication and the comparison of human communication with communication in other species, treating language as a resource differentially allocated and adapted in human societies on a certain generic base.

Comments. The sketch of kinds of means and frames of reference requires two comments. First, the broad categories of means and frameworks do not conflict or stand in isolation. A way of determining data may contribute to any frame of reference; a frame of reference may make use of any means. Field work, for example, is often thought of as a means to synchronic description, but its purpose may be to place a language genetically or to trace the process of acculturation; to study relations among geographical or social dialects; to determine the distinctive cognitive style of a language or to substantiate a proposed universal of grammar. Synchronic description is often based on contact work, but one may write grammatical rules for philologically interpreted texts or a reconstructed language or specify theoretically the universal parameters of grammar. Desirable as such interplay is in principle, in practice it may be obscured by specialization and controversy (as it has been on some occasions in synchronic and diachronic work); but in the long run interest in knowledge of languages prevails, especially in the work of great scholars. Every means that can contribute information is likely to find a place; frames of reference are likely to prove complementary. Such unity in diversity appears most often in work on a group of languages, be it Romance (see Malkiel 1964b), Dravidian, or Algonquian. Most linguists being specialists in some language group, such work is a source of stability and strength to the field.

Second, an exact analysis of kinds of work and their interrelationships would require a greater number of dimensions, accurately and systemati-

cally named. One set would distinguish study of syntactics (relations of signs within a code), semantics (relations of signs to referents), and pragmatics (relations of signs to their users). (The distinctions are those of Morris, see Greenberg 1948; Hymes 1964a, pp. 27-31.) Our discussion has, in fact, consistently noted study of use (pragmatics) as well as study of codes (syntactics, semantics). A second set of distinctions concerns the underlying dimensions of time, space, social group, system, and function. For these, one can use the Greek forms *-chronic*, *-topic*, *-gelic*, *-systemic*, *-telic* together with a prefix to specify in what way each dimension is taken into account. Useful prefixes include *a-*: without reference to the dimension; *mono-*: one reference point; *bi-*, *tri-*, etc.: two, three, etc., reference points; *poly-*: multiple reference points; *pan-*: all reference points; *syn-*: treatment as having common reference point; *dia-*: treatment as having continuum, or linked series of reference points. Such dimensions and terms make terminologically convenient a large number of necessary distinctions. Thus, studies that treat the history of a language in terms of discrete stages (e.g., bichronic) can be distinguished from studies that treat it as a continuous development (diachronic). Within the context of synchronic descriptive theory, one can distinguish the complex adequacy of Prague school theory (diatopic, diagelic, polysystemic, polytelic) from descriptive theory that implies a wholly homogeneous description (monotopic, monoagelic, monosystemic, monotelic).

We have broached something of the tasks of classification and explanation; more must now be said about each.

Classification of languages. Languages are often classified by their common internal features (phonological, grammatical, lexical) and in one or another of three ways: as belonging to the same family, the same area, the same type. Although each way implies a different sort of process and explanation, the three need not be mutually exclusive; in a limiting case, a set of languages may all belong to the same family, area, and type at once.

When languages belong to the same family they share a *genetic relationship*. Specific features of each are explained as due to retention (perhaps much changed) from a common ancestor of all. English, Frisian, Dutch, German, Icelandic, Norwegian, Danish, Swedish (and extinct Gothic), for example, belong to the same family, Germanic, in virtue of their descent from a common ancestor that is called Proto-Germanic. As it happens, that ancestor can be shown to belong to an older fam-

ily, Indo-European, whose common ancestor, Proto-Indo-European, may itself someday be shown convincingly to belong in yet an older family. The proportion of features that attest the genetic connection of languages may be quite small; what is required is that the presence of the features be inexplicable by chance or borrowing.

When languages are said to belong to the same language area (German *Sprachbund*), or convergence area, they share an *areal relationship*. Continued compresence in the same area may enable genetically related languages to maintain great commonality of content through shared innovations and mutual borrowing, despite long divergence from their joint ancestor; these languages may even increase their commonality after an earlier period of differentiation (see Hoenigswald 1960, pp. 155–157; Malkiel 1964a; Kroeber 1955). The most salient cases of areal relationship are those in which the languages are genetically unrelated. Thus the languages of the subcontinent of India belong to three distinct families (Indo-Aryan branch of Indo-European, Dravidian, Munda), but they share significant traits through sustained contact (Emeneau 1956; Hymes 1964a, pp. 642–650).

When languages are said to belong to the same type, one must notice what portion of their features is concerned. A *typological relationship* may be defined by one or a few traits of interest or by a distinct system or level (phonology, morphology, syntax, lexicon). Attempts to assign languages as wholes to types (a *language type* proper) have focused on grammatical or semantic characteristics or both. When specific features are investigated, a given language may, of course, fall together in type with quite different sets of other languages, depending on the features in question. (On genetic, areal, and typological classification, see references in Hymes 1964a, pp. 659–661, 651–653, 661–663, respectively.)

Classification of languages in terms of context and use is less well developed, a fact reflected in the absence of a comprehensive conventional terminology. There exists a scattering of individual terms not yet systematized. The dimensions of the subject can be sketched, however, along lines corresponding to those just followed, taking the genetic as concerned primarily with origin, the areal with co-occurrence, the typological as independent of either.

Some terms focus attention on languages as marked by their origin in particular circumstances of use. A *koiné* is a language that has arisen as a *lingua franca* by a merging of traits among a group of related dialects, as in the Greek *koiné* of Hellen-

istic times (from which the term comes). A *pidgin* arises by drastic reduction of one language, typically with admixture of another; it is by definition a second language to all who use it. A *creole* arises if a pidgin becomes and remains the first language for a group, expanding into a normal range of use. (Thus, by definition a creole was once a pidgin.) By virtue of their common origin in conscious invention, constructed languages intended for international auxiliary use (Esperanto, Interlingua, etc.) belong here.

Some terms group languages according to their relationships within a community or larger population. Some groups of Sephardic Jews in Greece, for example, used Greek at work, Hebrew in religious observances, and Spanish in family conversation. Together the three languages formed their linguistic (or verbal) repertoire. One general classification of the varieties forming a verbal repertoire distinguishes those associated with geographic and social differences and those associated with differences of activity, as *dialectal* and *superposed*, respectively. [On this and other aspects of use, see LINGUISTICS, article on THE SPEECH COMMUNITY.] Terms often distinguish range of use; “standard language : dialect” and “world language : vernacular” are two such pairs. The use of “language : dialect” has varied and is still unresolved, but the two terms are always correlated in such a way that dialect is the subordinate term—language indicating a variety with higher status or wider use or a set of dialects as a whole.

An important kind of co-occurrence is that analyzed by Ferguson (1959; Hymes 1964a, pp. 429–438) as *diglossia*: two mutually unintelligible forms of language are in use—one for government, literature, formal religion, and the like (the “High” form) and one for informal conversation, the home, and the like (the “Low” form). The two are part of the verbal repertoire of some, but not all, members of a society, many knowing only the Low form. The general description of language co-occurrence within nations has begun to be studied as a nation’s *sociolinguistic profile* (Ferguson 1966).

Some terms specify use without necessary reference either to origin or co-occurrence. One such term is *lingua franca*, a language that serves as a common medium throughout a linguistically diverse region. *Standard language*, as a consciously codified form of language, belongs here, considered in terms of its intrinsic characteristics and associated attitudes and functions (see Garvin 1959; Hymes 1964a, pp. 521–526, with references). Indeed, all terms that designate components of a

verbal repertoire or sociolinguistic profile may be specified and studied synchronically: the High and Low forms of a diglossia situation, languages of religion, trade languages, languages of concealment, slang, etc., can all be studied both in terms of the social circumstances of their origin and in terms of their co-occurrence with other varieties of language.

The uses and imports of the modes of classification are varied but ultimately interrelated. Genetic classification has a certain priority, as a background against which to interpret relationships of area and use and from which to guarantee the historical independence of cases for typological generalizations. As a mode of explanation of resemblances among languages, genetic classification has sometimes been set off against areal classification, as in the Boas-Sapir controversy (see Swadesh 1951; Hymes 1964a, pp. 624-637) and in the earlier California work of Dixon and Kroeber (see Hymes 1961a; 1964a, pp. 689-707). But in fact, the logic underlying the historical modes of classification makes them interdependent. This logic is to determine if corresponding features are (1) of independent origin (universals, convergent, chance), or (2) due to historical connection, and, if historical, whether (a) genetic ("cognate"), due to retention from a common ancestor, or (b) diffusional ("borrowed"). Neither genetic nor diffusional origin can be assumed, each must be proved, and proof of one excludes the other. Actual historical work must thus attend to both. There remain questions concerning what explanation to assign to particular kinds and amounts of data. Well-integrated grammatical traits and basic vocabulary are the best, though not infallible, test of genetic connection. Despite a priori controversy, the work of the great students of linguistic prehistory is in practice one of cumulative inference from all the available evidence.

Although the languages of the world have been provisionally assigned to genetic groupings, such work is far from complete. For most parts of the world new and better descriptions of languages will permit deeper penetration of the past, as will reconstruction of protolanguages by the comparative method. Anthropologists (Swadesh, Greenberg, Haas, and others) have taken a leading role in this work, dealing with both proof of relationships and development of method for the great time depths and remote relationships that face students of linguistic prehistory. If data permit, beyond proof of relationship lies establishment of relative chronology (subgrouping) among the related languages and of the location and perhaps some of

the cultural content of the ancestral language. Proof of borrowing may also lead to knowledge of relative chronology of relationship and the earlier location and cultural content of languages. Such work may provide a framework and hypotheses for prehistoric research with other lines of evidence, and of course it provides many precise examples of regularities and complexities of change, examples that have constantly been posed as problems for psychological and sociological explanation.

Studies of the American Indian languages of the Pacific Coast early revealed phonological areas where many distinct languages share systems containing few vowels and many consonants (including glottalized stops and voiceless laterals); and initial attempts to determine grammatical areas were made early in the century by Dixon and Kroeber. Neither in North America nor in the rest of the world outside Europe, however, has knowledge of areal connections gone beyond some notable individual studies. Increased interest in the structuring of interrelations of communities (such terms as "social field" and "intermediate societies") may stimulate increased attention to areal relationship as its linguistic counterpart (cf. Gumperz 1961).

Typological relationship may be linked to areal relationship, as when reconstruction of the Proto-Indo-European vowel system suggests a former areal tie with languages of the Caucasus or when it is proposed that proliferation of phonemes is correlated with fewness of speakers in areas of linguistic diversity, since persons in small communities learn the languages of their neighbors as a result either of accommodation or of exogamy, and in either way introduce among themselves phonetic habits that come to enlarge the phonological system of their language. Most typological classification points in one of two directions. It seeks to explain recurrent types in terms of the limited possibilities and internal interdependence of linguistic systems (e.g., laws of the sort, "If A, then B") and to relate such types to underlying generic properties of the human mind; or it seeks to delineate types in terms of the selective drift within a given culture history, as distinctive of a society or as characteristic of a sociocultural type. (Findings with regard to Hopi, Navajo, and Wintu, for example, may be seen as manifestations of an underlying outlook common to primitive society that Redfield dubbed "participant maintenance.") The two directions seem to alternate in attention, interest in distinctiveness having given way recently to interest in what is common, considered apart from sociocultural adaptation; but underlying commonality does not level the projecting dif-

ferences that show languages engaged in the histories and lives of those who use them. Both interests are required to explain language.

Classifications as to use (often dubbed functional classifications) are of obvious importance to any concern with the varying roles of languages in culture, society, and personality. Choice and role of language are particularly important in nationalism, political identity, state formation, economic development, and in literacy, education, international communication; and they are also important for changes in the valuation of language itself relative to other modes of experience and communication. New analyses and syntheses of what is known are greatly needed, but they are only slowly beginning to appear (see Weinreich 1953; Ferguson & Gumperz 1960; Fishman et al. 1966, pp. 424-458; Ferguson 1966).

Each principal mode of classification in terms of internal content may seem linked to a different frame of reference—genetic to diachronic, areal to diatopic, typological to syncritic—but something of their interconnection has appeared. Any instance of classification can be put into all frames of reference by asking: What are the underlying descriptions? How did the relevant features come about? Where do they occur? What are their defining characteristics? And in pursuit of historical explanation, the emergence, persistence, and sometimes extinction of families, areas, types, and modes of use are interwoven (see Hoenigswald 1960). Pidgins and creoles, for example, pose problems for theory of genetic and areal relationship and for generic interpretation of typological resemblances. In sum, each mode of classification is useful, indeed indispensable, for particular questions: the major questions of linguistic explanation join together all of the modes. To generalize what Boas once wrote (with genetic classification in mind): "the problem of the study of language is not one of classification. . . . Our task is to trace the history of the development of human speech" ([1920] 1955, p. 212).

For any one language, its features can in principle be explained in terms of a portion common to all languages as languages (typological-generic), a portion retained from an ancestral stage (genetic), a portion acquired from other languages with which it has come into contact (diffusional), all of these portions having adapted to each other along distinctive lines (typological-contrastive) in certain circumstances of use. In Sapir's words, "The formal configuration of speech at any particular time and place is the result of a long and complex historical development, which, in turn, is

unintelligible without constant reference to functional factors" ([1924] 1949, p. 152).

Explanation and import. Descriptions and classifications go but part of the way in explaining linguistic data and their import. At the height of the historical approach to language the maxim was offered that the only explanation of a linguistic form is an earlier linguistic form. When the Neo-Bloomfieldian descriptive approach was dominant, some found it humorous to be asked to lecture on the nature of language. One asked of languages not "why" but "what." Such particularistic extremes set in relief the more common belief of linguists that in describing and classifying they also are illuminating something beyond the data in hand. How illumination is to come, what it should be, whether it is doggedly sought for or comfortably assumed—all yield much of the drama of the development of linguistics. The quest, most generally put, has been for meaning in particular texts and cultures, for the course of history, for characteristics of the human mind—in effect, for human nature as manifest in the concrete, in history, and in essence.

While the crucial role of language in human life makes its scientific study of perduring relevance to such goals, it remains true that most of the time most linguists seek the illumination of data within their own domain. "Why" questions, explicit or implicit, have a range of answers from the facts of a given language to general principles of structure, from facts of retention and borrowing to general processes of change. Each mode of description and classification implies explanation of some aspect of languages through the relationships it recognizes and discovers.

For our purpose, the critical point is reached when pursuit of explanation leads to relationships extending beyond language, when language is to explain or be explained in relation to other disciplines. Here questions of the unity and future of linguistics are most sharply posed. It is not that there are no questions of unity within linguistics proper, of the integration of different lines of purely linguistic work, but we can consider such questions only as they are entailed by the question of unity within the larger field of linguistics.

The field of linguistics

As must any discipline, linguistics proper must be master in its own house—literally, autonomous; but autonomy can be compatible with either isolation or integration. It is a striking fact that insistence on the independence of linguistics from other disciplines contributes to disunity within linguistics

itself, for the independence is defined at the expense of some legitimate mode of studying linguistic data. Recognition of the unity of linguistics as a whole promotes recognition of its interdependence with other disciplines in the broader field of linguistics.

The many aspects of the import of linguistics and other disciplines for each other cannot be reviewed here; rather, we can consider what bases exist for integrating within a unified field of linguistics.

Unity and interdependence have long been recognized in principle, and often in practice, in the pursuit of historical explanation and philological interpretation, where one uses all there is to use. In the particular case, knowledge of customs, artifacts, social conditions, distributions, and environment plays a part inseparable from linguistic knowledge. The disciplines called upon to contribute include archeology, paleobotany, geography, folklore, comparative religion, numismatics, political and social history, and so forth. Where questions of the formation, movement, adaptation, specialization, obsolescence, and extinction of languages are concerned, dependence on social history is patent.

It is fair to say that the situation regarding unity is unclear outside the domain of historical explanation. A unity centered in structural analysis has gone far, integrating a great deal of work in linguistics proper, through recognition that structural formulations are prerequisite to many questions of history and use. There have been several efforts to base integration of a larger field on particular structural models (see references in Hymes 1964a, pp. 61-62), but none has prevailed. In other human sciences relevant to language one finds some use of linguistic models, some picking and choosing of linguistic results, some neglect of connection. The role of such disciplines in structural linguistics is similar; one finds some use of analytic models, some picking and choosing of results, some neglect or even denial of connection.

Such a situation may continue indefinitely. However, a larger unity within the field of linguistics can be attained; linguistic data must remain the focus, but the perspective brought to bear must encompass the gamut of relationships that determine the use of language.

The central requirement of such a perspective is that it focus on the integrity of the verbal message as an act. From such a focus there follows a series of consequences for conceptions of the object of analysis, consequences that have been partly indi-

cated with regard to synchronic, diatopic, and synchronic description, but that must now be explicitly drawn.

(1) Linguistic description has focused on the form of languages, neglecting the structuring of their use (*la langue* as opposed to *la parole*). The social sciences, on the other hand, have usually been concerned with language use, neglecting form. Consequently, most attempts to integrate language with culture or society have inevitably failed, for the terms of the relationship have been conceived as disparate abstractions. A grammar and an ethnography both treat verbal messages as data, but, typically, neither studies messages as having an integral structuring of their own. The one abstracts certain aspects of form, the other certain aspects of content (other kinds of form), as if they were historically disjunct products. Having put asunder, one may try to join together, but the form and process of speech, wherein the relation of language to culture and society is mediated, the cambium, as it were, of both, has not been incorporated into either abstraction. A unified field of linguistics requires study of the patterning of speech as well as of codes.

(2) Structural description has usually defined its object synchronically as a single homogeneous code or the abilities of an ideally fluent user of such a code in an ideally homogeneous community. Such simplification is useful when models of internal structure are being devised and single codes are being described in their terms. Models of the structure of speech must allow for multiplicity of codes—quotation within messages and switching between messages (of bilinguals)—and specialization of codes in different topics, occasions, roles, and institutions. A unified field of linguistics should have as its natural unit of study the speech community rather than the individual code.

(3) Structuralists have usually considered the relation of language to other aspects of life as only supplementing what normally counts as language structure. One looks out from the linguistic account, seeing its features as subject to variation or additional rules and restrictions. The best models do envisage extension of structural description from sentences to larger units—paragraphs, narratives, even conversations, and the many recurrent routines that make daily speech so much more predictable than the infinite potential of language would suggest. Even so, much remains undiscerned until one looks at the linguistic account from the standpoint of its additional functions in social use. In general, one cannot predict such functions from

relations of structure as ordinarily described; rather, each level of organization (function) reveals new structural relationships among elements of those below it. Modal particles, for example, may show structural relationships only when seen to join with features of intonation to serve an expressive function. No internal linguistic relationship brings together greetings, terms of address, insults, curses, request forms, and so forth; only social rules can show each to be a set. Thus the lexicon and phrases of a language can be wholly analyzed structurally only from the standpoint of the social level, for some sets within the network of contrasts into which they enter are socially defined. Moreover, the usual structural account, normatively generalizing, omits as ungrammatical some sentences that specifically and acceptably do occur in a community.

In sum, social situations, relationships, and purposes bring into being and maintain linguistic (and nonlinguistic) features and relationships among them. A unified field of linguistics must consider the structures of languages from the standpoint of a description of their contexts of use.

(4) Structural descriptions have usually taken the functions of language for granted. They have focused on the organization of language in the service of reference. The latter term is used here as distinct from both denotation and meaning. One discovers the denotation of an expression in its application on particular occasions; its reference in a dictionary, which states criteria for its application; its meaning in the total import of the situation (see Firth 1935). In effect, most description has based itself on just those speech acts in which grammatical sentences are used with full referential force, neglecting the poetic or expressive facets of speech acts, for example, and the many messages in which (in Sapir's phrase) it is as if a powerful generator were hooked up to run an electric doorbell.

Descriptive theory has generally taken the social adaptation of language for granted as being everywhere the same. The images of one language per community and the infinite potential of any language (as well as the struggle against misconceptions of the adequacy of "primitive" languages) have led some to a militant egalitarianism that refuses to consider the obvious fact that the potentials of languages are not developed equally or in identical directions; that a language is often specialized in certain roles, not all; and that the valuation of even a native language may vary from community to community: free resource here, scarce good there; integral to unity here, easily

abandoned there; an object of pride here, without prestige, even disvalued, there; and so forth.

Models of internal structure may ignore these variations in adaptation: reference is indeed the central function underlying grammatical structure. It remains that a unified field of linguistics must take the functions of language (both in speech acts and in communities) as problematic, and it must develop the concepts and methods for their study. (On functions in speech acts, see Jakobson 1960; Hymes 1962; 1964*b*; on functions of languages, see Hymes 1961*a*; 1966; Ferguson 1966.)

The patterning of speech, from the standpoint of communities and contexts of use and the gamut of functions that speech serves in particular acts and groups, as men enact and transcend their situations, is a dimension of a "totalizing" approach (Sartre 1960) that calls for case studies and analytic comparisons going beyond any line of work familiar to us now; yet the need for such an approach can be indicated readily with regard to several problems.

Understanding the acquisition of language by children is of both theoretical and practical importance. Some seek to account for linguistic competence as the process of a child's learning to use any and all grammatical sentences in a language; but such a conception of a child's competence at once omits and idealizes. It omits, in that a child competent in all sentences still would be master of none, not knowing when, where, and how to speak, and about what, to whom, not sharing the attitudes and valuations of the community toward language. It idealizes, in that mastery even of internal structure is a matter of degree, affected at its root by social environment. To explain and affect the communicative competence of children requires the totalizing approach just indicated.

The relation of language to thought is persistently of concern. While the two are far from identical, experience and experimental evidence demonstrate that features of a language do shape behavior and thought. In the long run a language is shaped by the needs of its users, but in the short run the acquisition of experience through a particular language and the need to call on ready linguistic categories partly shape men. All men potentially perceive and think much the same; actually, they notice, store, and recall information mainly in familiar verbal grooves, although the aspects of life for which this is true may vary from society to society. In a multilingual world, moreover, a given language may be the matrix of thought to one person but only its superficial, occasional garb to

another. The effect of a language on thought and behavior cannot be inferred from the language alone, but on the basis of a sociolinguistic description of its place in social and personal life (see Hymes 1966).

Verbal art—poetry, narration, oratory, rhetoric, dialectic—is universally made possible by language. A language, indeed, may be viewed as an aesthetic product (Sapir 1921). The forms possible to a verbal art are conditioned by the language, which is also the indispensable means to their study. With the new interest in metrics, poetics, and stylistics as approached through structural linguistics, and with the aid of folklore and anthropology, a truly comparative literature, global in scope, may emerge. And, if seen as not a matter of forms and texts alone but of symbolic action as well, verbal art becomes of special interest to the human sciences generally [see *DRAMA; INTERACTION, article on DRAMATISM*]. The aspects of human nature that underlie the universality of verbal art; the extent to which abilities are cultivated or left dormant, and why; differences in the valuation of language as an aesthetic medium, relative to others (music, dance, ritual, plastic arts) and to other concerns; the structuring of performances and the possibilities that such structures show major areal groupings, express particular aspects of social life, and reflect particular conceptions of the uses of language—all such concerns require an approach through texts as situated in contexts.

The question of the origin of language has returned to prominence, even though theory in this field is in one sense a myth, a projection into time of assumptions on the essential nature of language and its meaning for man. Linguistics proper can prescribe the elements, generic to all languages, whose origins are to be accounted for. (There is the possibility also that some elements of the last stage of the emergence of true language might be recoverable genetically.) A theory of origin must draw on all possible lines of evidence—biological, psychological, archeological—within a theory of the evolution of man. Since language emerges within an ongoing communication system, it is crucial to specify the conditions of selection that would have been operative. Comparison of human communication systems with those of primates is indispensable; so also is comparison of human communication systems among themselves. Studies that analyze comparatively the uses of language are also necessary, in that they bring into view not only what language may be used for but also what it need not be used for in the transmission of cul-

ture and cooperative activity (e.g., some societies seem not to require language for hunting or transmission of tool-making traditions). It is likely that a very limited code, less than true language, sufficed in small homogeneous groups until relatively late in prehistory.

With regard to linguistic conceptions of the unity of man, three perspectives can be distinguished—one envisaging unity through a common origin in the past, one envisaging unity in terms of a common essential nature of language in every time and place, and one envisaging a prospective unity in the context of an emerging world society. The three perspectives are complementary, but the first was more prominent in the nineteenth century (although carried on today in the work of Swadesh and others); the second has been more prominent with the emergence of structural linguistics in this century; and the third is coming into prominence with the increased attention, theoretical and practical, to a sociolinguistic approach. For a long period of human history the differentiation and dispersion of languages was the dominant process, but reintegration and mutual adaptation of languages within more complex social systems have increasingly superseded it. Indeed, genetic differentiation may never occur again. The processes of reintegration and mutual adaptation have accelerated within the same period that general linguistics has emerged, and many of the varied phenomena that attract sociolinguistic attention are aspects of the development of a single modern world—the correlated standardization of national languages; acculturation of dialects and of whole languages; the emergence of pidgins and creoles at the frontiers of mercantile activity and colonization; the efforts to construct rational international languages; the growth of language academies and bourgeois notions of correctness; the cultivation of intertranslatability among the languages of Europe; the challenge to the stable diglossia of older philological civilizations by proponents of “Low” forms of speech; the extension of writing and literacy; and so forth. If these phenomena are to be related within linguistic theory, that theory must approach communities, functions, uses, and adaptations in a way that indeed takes on the character of an evolutionary perspective.

In one view, to be sure, the concept of evolution does not apply to language after its origin. Certainly no subsequent biological selection is apparent (although suggestions concerning a genetic basis for a few sounds have been made). From the standpoint of sociocultural evolution the matter is differ-

ent. In their make-up, use, and survival, languages have been part of the specific adaptations of societies to environments, cultural contacts, and internal changes. And if all languages are equivalent in fundamental structure and potential capacity, languages as actually developed and available to their users have come to differ in ways that correspond, in part, to general stages of the cultural history of man. One mark is development in terms of the metalinguistic function (language about language), as seen in the development of linguistics itself. Some grammatical features and phonological characteristics seem present at one or another level of sociocultural integration and not at others. Most clearly, the differentiation of society is necessarily accompanied by technical elaboration and differentiation in vocabulary and syntax of a novel order. Recently, such development has been carried to the point of providing the linguistic tools for universal science and an incipient world civilization. Science itself is a key factor, for the languages in which it can be conducted (the small subset that may be called "world" languages) share the novel obligation that there be a name for everything in the universe: botany must leave no plant unnamed, ornithology no bird, ethnology no tribe, and so forth. While mathematics and logic have become what may be considered "postlanguage" developments, it remains true that they must be interpreted in natural languages and can be interpreted only in a few of them. The ideal of universal translatability is most nearly realized in these languages (as languages into which translation is made). These languages of course confer no necessary superiority or advantage on any individual. A user of English may be less able to master experience verbally and less skilled in language use than a user of a language quite local in scope. Even so, these observations must be controversial as they stand, offending as they do the widespread belief in the equivalence of all languages in complexity and function (see Hymes 1961a; 1964c). The practical importance of such observations is manifest, however, in many issues of education and language policy, both in industrialized and industrializing nations. It should be clear that a modern evolutionary approach to society and culture fails to be adequate, theoretically or practically, if it excludes language.

Linguistics will play a part in the social sciences in the future if only because language so often must be the means of access to other things. Interest in language for its own sake as an aspect of

man and society will continue to be an integral part of anthropology and psychology, and, increasingly, of sociology. The novel contributions that linguistic results and linguistic methods can make will be a constant source of such interest, but if an integration within a larger field of linguistics is to be realized, the social sciences themselves will have to contribute results and methods to the study of language. The prominence of the terms "ethnolinguistics," "psycholinguistics," and "sociolinguistics" since World War II augurs such a trend. While each term mediates between linguistics and a particular discipline, the set in total mediates between linguistics and the social sciences as a whole, drawing the two together. The outcome of such a unity will be a linguistics that is truly the science of language.

II

HISTORICAL LINGUISTICS

Although consecrated by over a century and a half of use, the term "historical linguistics," as a designation of a discipline, is something of a misnomer, because the most exciting and controversial operations of that discipline concern the reconstruction of language, i.e., prehistory, rather than documented history. For this reason, perhaps,

Saussure, in his search for a label that would neatly contrast with the newly discovered "synchronic" perspective, suggested the qualifier "diachronic," which, possibly as a result of its paleness, later proved less than successful (1916). In the mid-twentieth century, it might be most apposite to speak of "genetic linguistics" in reference to the entire domain, reserving the alternative designation "glottodynamics" for the hard core of general doctrine governing the analyst's major operations.

Historical linguistics is very often equated with "comparative linguistics"; to the extent that the tracing of genetic relationships involves some confrontation of an earlier with a later stage of the same language (of Old English, say, with Middle or Modern English), a measure of overlap is indeed unavoidable. For practical purposes, however, it seems advisable to refer to comparative linguistics only where several cognate languages—ideally, they should be observed at the same time level—are jointly analyzed in an effort to arrive at the parental tongue, as when proto-Central Algonquian is reconstructed from available records of Sauk and Fox, Cree, Menomini, and Ojibwa. Of course, it is equally legitimate to engage in the typological comparison of languages with no thought of historical reconstruction and regardless of the presence of any kinship ties—see Bally's classic confrontation of Modern German and Modern French (1932) and the currently fashionable "contrastive" grammars.

Historical and comparative linguistics reached their first peak of development in the nineteenth century, although there were some rudimentary attempts in western and central Europe from 1500 to 1800. Language history, in contrast, represents a relatively new genre of research; its roots are in broad-gauged introductory chapters to technically worded historical grammars. In terms readily understandable to layman and beginner alike, language history interweaves austere linguistic analyses with discussions—rarely devoid of grace—of social, economic, broadly cultural, demographic, and literary conditions prevailing at the successive time levels, allowing also for remarks on the philological state of transmission. At its best, as in Migliorini's masterpiece (1960), language history excels at tracing the vicissitudes of a single language viewed within the matrix of the corresponding highly literate national culture.

The individual facts ascertainable through the various analyses devised by historical linguists lend themselves to two entirely unrelated kinds of synthesis. Certain language forms can be lifted out of their original philological context (which alone, in most instances, made their secure identification

possible) and can be arranged on a higher plateau of abstraction so as to illustrate broad aspects of a specific linguistic transformation, e.g., the development of sounds, derivational molds, lexical meanings, or syntactic structures from stage A to stage B of the given language. Climbing to a still higher level of generalization, the analyst is at liberty to abandon even the context of the specific language at issue and to cite the modifications observed, for the sake of their illustrative value, in a general methodology of linguistic change. On the other hand, the slivers and nuggets of information obtained through stringent linguistic (in particular, etymological) analysis may be deftly inserted, as highly prized items, in the grandiose mosaics pieced together by patient and versatile historians. These items of information are similar to the fragmentary bits of knowledge collected by physical anthropologists, archeologists, folklorists, and others who attempt to recapture the elusive past.

Traditionally, from the days of such pioneers as the Germanist Jacob Grimm and the Romanist Friedrich Diez to that towering Indo-Europeanist of the early twentieth century, Antoine Meillet, the two conspicuously parallel tools of research in diachronic linguistics have been the manual of historical grammar and the etymological dictionary—the one providing a tightly ordered macrocosm and the other a loose kaleidoscopic array of microcosms. The full-sized historical grammar—not infrequently a multivolume venture—embraced phonology (with excursions into prosody or accentology), inflection, "word formation" (i.e., affixal derivation and composition or their counterparts in non-Indo-European languages), and syntax. These centered, in ever widening circles, on the word, the phrase, and the sentence. An abridged version was limited to phonology and inflection. Inflection and the "syntax of the word" are so closely adjacent that they tend to merge, and a few scholars have gone so far as to consolidate all of morphology and syntax into the single domain of "morphosyntax," which forms the hard, inalienable kernel of linguistics. Excursions into semantics, metrics (also, through the inclusion of tropes, rhetoric, or poetics), and stylistics—the last-mentioned more loosely organized and defined in a variety of ways—have at all times been regarded as optional rather than obligatory. Only in recent decades have grammatical and lexical studies drifted apart so sharply in techniques and appeal as to render problematic any joint ventures in the immediate future.

The relative stabilization of historical linguistics in the period 1850–1925 had the advantage of producing a far-reaching standardization in its termi-

nology; this, in turn, by virtue of the comparability achieved, has invited and furthered at every step the confrontation of older and more recent studies, a procedure that has become more difficult in the last three decades. The long-unchallenged pre-eminence of central European scholarship in this field is mirrored by the wide acceptance of such technical terms as "umlaut" (metaphony) and "ablaut" (apophony), while other German labels, potentially just as helpful (e.g., *Lehnwort* "assimilated borrowing" versus *Fremdwort* "unassimilated borrowing"), have enjoyed no such popularity. Early standardization was particularly beneficial in certain special types of nonverbal symbolization, e.g., quotation marks for meaning, italics for quoted forms, boldface for transliteration into another alphabet, small capitals for an ancestral language (e.g., Latin versus Romance vernaculars), large capitals for epigraphic material, square brackets for phonetic transcription, asterisks for hypothetical forms, and, above all, the two directional signs: > "changes into" and < "descends from."

Before long, the success of these symbols led to a temporary staleness, except where the stagnation was relieved by the introduction of signs manufactured by the more aggressively imaginative structuralist school (e.g., slanted lines for "phonemicization"). Thus, few historically oriented scholars have bothered to discriminate typographically between two logically distinguishable hypothetical forms: (a) those undocumented, yet assumed to have existed (*) and (b) those expressly presented as non-existent (.). Again, although few experts would deny the sharp cleavage between phonology and morphology, historical linguists have failed to capitalize on the possibility of contrastive symbolization of phonological versus morphological shifts.

To the extent that genetic linguists are concerned with historical situations, unique by definition, they can resort to the device of "model formation" only on a limited scale. In a way, any reconstruction of genetic relationship between languages or dialects involves a generous measure of schematization aimed at eliminating those details that would tend to blur the broad outline. One can visualize an entirely different kind of model: instead of focusing attention on concrete territories (at historical stages) or avoiding any commitment to the speakers' habitat (at prehistoric stages), the analyst may decide to invent imaginary countries with a sharply profiled distribution of coastlines, wastelands, mountain chains, ports of entry, emporia, cultural shrines, etc. He can further posit a certain succession of political, socioeconomic, and strictly linguistic events (say, invasions, retreats into the

hilly inland, reconquest of coastal lowlands, splits into dialects) and project them onto the imaginary area, excogitating in abstract terms the likeliest concatenations of linguistic reactions to these pressures. By sharpening the analyst's alertness to possible and probable intricacies under artificial conditions that are relatively simplified, such schemata can prepare him for successful inquiries into real-life situations, incomparably more complex.

It should be emphasized that the postulate of historical uniqueness is not easy to reconcile with the search for evolutionary universals in the realm of language. However, the prospect of discovering such universals has for many decades been a source of constant titillation. One classic example is the often-observed correlation of word order (and comparable syntactic devices) with the available wealth of inflectional endings. Clarity and economy demand that, if relationships between members of a clause can no longer be expressed unequivocally by means of the endings (e.g., as a result of phonetic erosion), a stiffening of word order should provide an adequate substitute. Also, etymologists have discovered that, of all form classes, adjectives, on balance, tend to present lexical nuclei most resistant to identification. In addition, semanticists report that fluctuations and changes of meaning undergone by verbs exceed, as a rule, those to which a typical noun would be subject. The difficulty with trying to establish absolute universals is that each such attempt presupposes the testing of hundreds of languages. On the other hand, characteristic samples would suffice to identify tendential universals.

As in all evolutionary sciences, the question of purposeful, or oriented, change is at the heart of the philosophy underlying any genetic analysis of linguistic data. Linguists are sharply divided on this matter of teleology: the great Danish theorist Otto Jespersen and the founders of the Prague school categorically affirm the teleological principle (a few visualize a trend toward general improvement achieved through refinement, simplification, and economy); others, particularly Bloomfield (see 1933) and a whole generation of American linguists claiming allegiance to his doctrine, just as vehemently deny it. Discernibly different from the teleological approach, although occasionally confused with it, especially by opponents, is the idealistic slant (characteristic of Benedetto Croce's school in Italy and Karl Vossler's in Germany), which stresses the primacy of the speakers' thinking over their speech habits and grants them in the process a much wider margin of initiative and of control over linguistic change than would be ac-

cepted by believers in the pre-eminence of "blind forces" or those (such as Whorf) who view the configuration of a grammatical structure as a prime determinant of thinking and perception. The more literate the speaker and especially the writer, the stronger the case for the idealistic approach; in analyzing "graphemically" the comportment of ancient and medieval scribes, one can hardly fail to distinguish between what they aimed to achieve and what they actually accomplished.

Descriptive and historical linguistics

Basic to all operations in historical linguistics is the view which the analyst holds of the configuration of the speech community under study and of speech communities in general. This was clearly sensed by Bloomfield, who, in his influential book *Language* (1933), without disregarding the varying density of communication or denying the complexity of certain speech communities, impressed upon his readers the need to reckon with a far-reaching uniformity of speech habits. Similarly, in presenting the comparative method, he leaned toward favoring those situations that exhibit clear-cut dialect splits, without denying occasional alternatives. However, many younger scholars have recognized that the link holding together language communities is frequently mere similarity rather than actual homogeneity of speech habits, a point fraught with major implications for the geneticist. It is further held that bilingualism and even trilingualism are more widely disseminated the world over than is strict monolingualism, an assumption that demands flexibility in dealing with a multitude of diversified and changing situations. Thus, two groups speaking language X—one composed of members who have from infancy also mastered language Y and the other containing persons who happen to be constantly using language Z in certain social contexts—are unlikely to react identically to any incipient innovations spreading from a monolingual zone. (One also readily conceives of innovations arising at the intersection of languages.) One final argument in favor of fluidity in the object observed and elasticity in the method applied to its elucidation is the discovery that many areas commonly assigned *en bloc* to certain languages often lack such "natural boundaries" as might preserve a community of speakers in quasi-hermetic isolation. The emergence of such zones is due rather to conflation, i.e., to successive reapportionments of neighboring territories, each initially sheltering a different language or dialect. Therefore, unless perfect leveling subsequently ensues, one may detect beneath the present-day "roof"

bracketing the dialects remnants and splinters of their original phonic, grammatical, and lexical systems in almost kaleidoscopic confusion.

In linguistics, the relation of the descriptive (or synchronic) to the historical (or diachronic) perspective has been the subject of considerable speculation and discussion, the consensus being that descriptive analysis bears preponderantly on simpler, less opaque situations. From this nearly unanimous opinion several discrepant conclusions may be drawn. Some experts maintain that new techniques, such as the structural method, should be tried out first on horizontal, later on vertical, slices of linguistic material. There are those who visualize a historical structure as a succession of descriptive structures superimposed on one another. The main difficulty in designing such an edifice lies in the fact that certain features structurally less than significant at one evolutionary stage may suddenly acquire conspicuous importance during transition to the next stage. Thus, the descriptivist is free to assert that in words like *danc-er*, *kill-er*, the ending *-er* as the carrier of an identifiably specific meaning ("agent") represents a derivational morpheme, while in *hamm-er*, *pinc-er*, *rudd-er* the same sequence of sounds plays no comparable role. But the historical linguist, while acknowledging this distinction on certain temporal plateaus, must at all times reckon with the strong possibility of joint actions, inextricably interwoven, by homonymous genuine suffixes (such as the *-er* of *kill-er*) and mere suffixoids (the *-er* of *rudd-er*). One consensus is worth mentioning: from the minute inspection of any given state of a single language the experienced analyst can tentatively extract almost as much information on its earlier stages ("internal reconstruction") as he can from comparing that language "externally" with its congeners.

One way of doing justice to both perspectives has been to engage in a "stairway projection"; among the practitioners of this novel approach one may count such seasoned experimenters as Otto Jespersen (for English), Antoine Meillet (for Latin), and Walther von Wartburg (for French). This particular method of intricate surgery affords glimpses of the consecutive periods of the chosen language, slanted alternately in the descriptive and in the historical direction. The implication of this design is clearly that one may distinguish between periods of relative rest and stability and others marked by spells of stress and strain.

One salient difference between the descriptive and the historical approach in linguistics is that the former in most instances enables the researcher to operate with a finite corpus, an intentional se-

lection over whose scope he retains a modicum of control, while the latter often bears on an irredeemably fragmentary volume of data. The ability to work with lacunary material and a certain flair for filling in gaps thus become important prerequisites for success in linguistic reconstruction, just as they are for research in geology, paleontology, and paleobotany. Developments are contrastively symbolized by solid lines (documented) or broken lines (hypothesized); however, the latter do not invariably represent initial, prehistoric segments of trajectories. An archaic stage A may very well owe its transparency to the realistic, readily adjustable spelling habits of the scribes concerned; conversely, stage B, although temporally closer to the beholder, may become nebulous, because the scribes of that period, plagued by conservatism, or subject to an inferiority complex, may have endeavored stubbornly to cling to the orthographic norms of their predecessors ("etymological spelling"), while the actual speech processes ran their course with unabated speed; then again, stage C may mark a vigorous return to graphic realism, entailing the relative translucency of actual speech events. A vivid illustration of these three phases is provided by early Latin, late Latin, certain varieties of "low" and medieval Latin, and, on an overwhelming scale, the budding Romance vernaculars.

It also happens that some word of unmistakably Latin provenience which, judging from its "normal" transformations, must have been in constant use over two millennia, disappears from written records in the fifth century, only to re-emerge a thousand years later. In cases of this kind, the literary genres of the extant texts act as prisms or filters, often seemingly capricious. They may long repress a word, keeping it submerged until there arises some opportunity—socially or aesthetically controlled—for its definitive surfacing into the standard language.

Trajectories of linguistic change

Systematic inquiry into the configuration of trajectories has not yet outgrown the stage of trial and error. Where regular phonological change occurs, older notions of strictly gradual transitions do not apply. Between, say, the Latin *ū*, as in *pāru*, and the French *û*, as in *pur*, it is no longer admissible to posit an infinity of intermediate nuances of the stressed vowel without concurrently accepting some kind of cutoff point at which a vowel already markedly fronted, but still representing no more than an unusual variant within the phoneme /ū/, must have become a member, decreasingly erratic, of the sound family constituting the phoneme /ū/.

In other words, structural thinking forces us to recognize the interaction of slow-working phonetic *rapprochements* and more or less sudden occasional jumps. This composite schema guarantees the semblance of a close-knit system to a language at any moment of its growth. Thus, the graduality of development—not superseded, but only qualified and hierarchized—remains a vitally important assumption. Significantly, the hypothesis that the shift *ū* > *û*, eminently characteristic of the transformation of provincial Latin into French, is traceable to the contributing agency of Gaulish cannot be refuted by the argument that the Celtic language in question lacked a fully developed /ū/ in its own system. It would have sufficed for the local substratum language, at the start, to have slightly deflected the Latin *ū* from its original status of a high back vowel in the direction of *û*, thus producing a kind of chain reaction or even an accelerated advance along a straight line.

In yet another context, the configuration of a trajectory of linguistic change, properly interpreted, may be revealing. If the changes due to associative interference were to be plotted on a chart, some of them might give the impression of a bizarre zig-zagging curve. On such a chart a relatively level line may suddenly start climbing as a result of an outside pressure, a "disturbance," until it reaches a certain peak. Then the language's inner mechanism (e.g., the total weight of its inflectional paradigms) may begin to wipe out the irregularity, causing the line to drop until it reverts to its original direction. If in such an up-and-down movement, anteceding the advent of trustworthy written texts, the descending stage completely absorbs the effects of the ascending stage, it is quite impossible to detect the original disturbance. If the down movement falls short of counterbalancing the aberrancy or overcorrects it, there is bound to remain in its wake a residue of startling "exceptions." In case the irregularity happens to erupt at the very start of the written tradition, it may appear baffling in retrospect that the ancestral language and its eventual modern product should be in perfect mutual agreement while at such sharp variance with the intermediate step, which then, in fact, fails to perform any "mediation." Thus, the Latin third person singular imperfect ending *-ibat* (originally *-iēbat*) cast off in early Romance speech *-ia(t)*, which to this day survives in Spanish as *-ía*, a safely predictable form, but paradoxically it produced instead, in early Old Spanish, *-ié*, a variant difficult to reconcile either with its antecedent or with its sequel. Investigation (Malkiel 1959; 1964) has disclosed that the rise of *-ié* simply marks a minor temporary

deflection (of ascertainable origin), ultimately neutralized, while the later form *-la* represents far more faithfully the continuation of a basic trend.

Closely allied to the concern with the convolution of trajectories is the attempt, assuming a certain more or less steady rate of attrition in the core lexicon, to draw from parallel analyses tentative conclusions as to the degree of kinship between congeneric languages and the approximate date of their split. This approach, which rode the crest of a temporary vogue in the 1950s, has become known, broadly, as *lexicostatistics* and, with special application to dating, as *glottochronology*. Exaggerated claims, especially the attempt of some practitioners to place these techniques on the same pedestal as the rigorous study of sound correspondences, have led to quick disenchantment and virtual abandonment of the method.

Sound change

For better or worse, the vicissitudes of historical linguistics have been intimately linked with the theories of sound change. The recognition of regularity in these transmutations has been hailed as a milestone along the road to progress (cf. the radical programmatic statements of the "neogrammarians," or *Junggrammatiker*, circa 1870) or, more intransigently, as a touchstone of stringent scientific thinking. In the compressed classroom presentation of historical linguistics, lecturers have traditionally inclined toward concentrating on "regular sound changes" as the discipline's irreducible hard core. In the separate quarters of humanists and anthropologists alike, this rigid attitude has for decades contributed toward producing the impression of linguistics as a highly abstract subject, almost forbiddingly abstruse and, above all, divorced in its style and tone from cultural history, to say nothing of its aloofness from the realm of arts and letters. Moreover, because most provisional rules or "laws" admitted of a few exceptions and some of countless ones, there was for a while a widespread apprehension that the "regularists" were actually propounding some kind of mock science.

In reality, there exist several categories of sound change, each fairly autonomous—but not entirely so—and tied to diverse facets of human comportment and different levels of a speaker's consciousness. The immediate goal of linguists is to discover one workable formula for presenting these interconnections, however tenuous, and another for discovering the elusive ties of sound change categories to discrete mental processes.

The techniques of accurately circumscribing individual sound correspondences that are inherently

limited in time and space can be traced to the nineteenth century. By contrasting the French *mer* ("sea") and *père* ("father") with their Latin prototypes *mare* and *patre*, the analyst learns that the Latin *a* tended, by and large, to yield *e* in French. Further refinement of this first approximation is within easy reach. The discrepant first vowels in *père* and *parrain* ("godfather") (originally *parrin*, from *patrīnus*) alert the observer to the possibility that the shift *a* > *e* hinges on a crucial accentual condition, while comparison of *père* < *pa-tre* with *part* < *par-te* dramatizes the share that the configuration of the stressed syllable may have had in an obvious bifurcation, depending on whether that syllable ended in a vowel or a consonant. By examining with scrupulous care all seemingly aberrant developments (amenable to observation with optimal results in Old French), the analyst isolates, step by step, the specific phonological ("internal") factors that must have presided over the evolution, erratic at first glance, of (*il*)*lāc* ("there") > *là*; *paupere* ("poor") > *povre* (modern *pauvre*); *clāuu* ("nail") > *clou*; *aqua* ("water") > *eau*e (modern *eau*); *palus* ("pole") > *pieux*; *caput* ("head") > *ch(i)ef*, etc. Comparably detailed breakdowns can be established for all other Latin sounds viewed in their transmission into a chosen "daughter language," and, by way of effective control, the linguist is free to reverse the perspective and select as a given the basic sound unit of the daughter language, assigning to himself the task of individuating its sources.

But this classification marks only a first step, yielding at best a tidily subdivided inventory of raw facts. The preliminary classification is nonexplicative, lacks statistical underpinning, fails to throw into bold relief parallels, convergences (including some that are partial or have been arrested), and, worse, concatenations of events, and does not begin to take into account other forms of sound shift. Such taxonomy disregards several broad or distinct categories of internal linguistic change. Moreover, it is not elastic enough to do justice to the various external pressures (demographic, social, educational) on evolutionary trends in speech and in the written word as well. It is in these directions—many of them affording fruitful contacts with a whole spectrum of other disciplines—that the chief advances of late-twentieth-century research are bound to lie.

The following are a few illustrations of research in progress and tempting prospects of investigation. Alongside regular phonetic change (akin to Sapir's "drift") scholars have placed sporadic shifts (also called spontaneous and saltatory), such as metathesis, the transposition of a sound or intermuta-

tion of two sounds, in contact or at a distance, hapology, the elimination of one or two successive segments partially identical, and certain dissimilatory processes. None of these, it has been argued, is confined to a specific locus or span of time, i.e., they are all, at least latently or tententially, pan-topic and panchronic. Granted the fundamental validity of this distinction, there arise several questions and second thoughts. Does the sound system of a language at a given stage—or, alternatively, its pattern of regular changes—typically stimulate or block sporadic shifts, or does it let them take their own course? Could it be true that, for all their uniqueness, regular sound changes, in any random selection, display such strong proclivities in a few characteristic directions that one discerns in them certain universals? Is it legitimate to grade the regularity of sound change (not as an ideal postulate, but as a bit of reality) and to contrast “strong” expectation of outcome, most likely to occur in monolithic societies, with “weak” predictability, attributable to, say, loose confluences of dialects, regional or social? Does such a state of prevalent weakness tend to intensify sporadic shifts and to invite even an excess of lexical contamination? Should frequency of lexical occurrence, or at least of incidence in actual speech, rank as a factor contributing to the degree of regularity, especially where a particularly unusual sequence of sounds falls into no broader pattern of immediate appeal? Can the exigencies of inflectional patterning slow down the pace of a sound change or counteract it to the point of weakening a phonetic “law”? Do other demands of this kind carry sufficient weight to set in motion or to accelerate potential and, especially, incipient sound changes? If the answer to the last two questions is affirmative, can one uphold the view that phonology operates in practically hermetic isolation? Specifically, is it still permissible to resolve the phenomena of genetic phonology into a neat interplay of sound relationships—to be precise, into an alternation of states of equilibrium and states of unrest or tension, to the virtual exclusion of all rival forces? Does it make sense to arrange sound changes in their presumed chronological succession (Richter 1934) without explicit forewarning that such sequences neither invariably presuppose nor necessarily imply the flow of one change from another or from the sum of all others already completed? Can one, in such contexts, ignore with impunity certain extraneous factors such as pressure of morphological paradigms and deflections from the straight course through associative lexical interference?

From earlier incidental mention it is clear that there are other kinds of change affecting linguistic

form and, consequently, reflected in the sounds as the obligatory carriers of that form but not here caused by purely phonetic conditions. The most important of these supervenient categories of change is analogical. Speakers make adjustments bearing either on the configuration of a grammatical paradigm or on the shape of a single word; in the latter eventuality, both the radical and the affix are open to modification. Typically, such adjustments follow upon sound change; only by way of exception may one suspect them of impinging, as prime movers, upon sound development. Since analogical changes involve, by definition, associative interference, they seem to occur on a higher level of awareness than straight sound changes; thus they invite psycholinguistic analysis.

Sound symbolism constitutes yet another autonomous category, of slightly controversial status. To the extent that sounds, in symbolic context (and nowhere else), are credited with conveying messages of their own, this marginal category represents a tenuous bridge to semantic change, ordinarily removed from the realms of articulation, acoustics, and auditory perception. Sound symbolism may be absolute or relative. The former category prevails if the analyst attaches, cross-linguistically, an unvarying evocative value to, say, a high front vowel or to a hissing prepalatal consonant; the problem then is to ascertain whether speakers will allow words endowed with major connotative force, through such ingredients, to participate in normal sound shifts at the cost of heavy loss in suggestiveness. The effects of relative sound symbolism are conditioned by the given phonological system; thus, in a language generally averse to long consonants an occasional geminate may boast “expressive” value (which it would otherwise lack). Again, the language historian is curious to learn how speakers can maintain a word enhanced by such a feature in this privileged status amid the welter of pervasive transformations. At this juncture one welcomes contact with information theory.

Pressures for linguistic change

Entirely different from the classes of change are the categories of forces that are apt to produce changes of any kind. But the linguist's operational procedure in tackling this new problem remains essentially unaltered: again his dual task is first to isolate the forces in question and then to discover the closest available approximation to the formula for their interplay.

It is customary to divorce the internal from the external forces at the outset, notably because the separate inquiries into them seem to appeal to radically different minds. In the former group one can

readily distinguish two drives, sometimes acting in polar opposition—one toward economy of effort, the other toward clarity. Economy, syntagmatically conceived, aims at the speech act; in paradigmatic perspective economy relates to the acquisition of, and sustained command over, neuromuscular skills. The former type determines the course of most assimilatory processes, contextual by definition (e.g., Latin *actu* > Italian *atto*) and governs the choice of those glides and buffer consonants that serve to smooth away troublesome contiguity (in Old Spanish viewed in its relation to Latin: *hōnōrāre* > *onrar* > *on-d-rar* versus *fēmīna* > *femna* > *fem-b-ra*). The latter type precipitates mergers of phonemes in the system where continued distinction between them would produce only a meager yield (/ā/ and /ē/ in older Parisian, /ɛ/ and /œ/ with increasing momentum in present-day Parisian). It also dooms to extinction minute groups of words displaying an infrequent sound or combination of sounds.

A groping search for increased clarity may be behind most dissimilatory and haplogistic processes. It accounts, as would no other supposition, for the speakers' readiness to augment their vocabulary (in an effort to reduce lexical polysemy) and to accept longer and more cumbersome syntactic structures (in a recoil from ambiguity). It is perhaps at this point that the newly achieved refinement of transformational grammar would most benefit the classic researches conducted by geneticists. The same urge for increased clarity ultimately justifies the sometimes successful flight from harmful homonymy or from its mere threat—the nearest escape routes being substitute words borrowed from neighboring dialects and reinterpreted within one's own cultural heritage, and words freely invented.

After one deducts the two-pronged quest for maximum economy and clarity, it is the residue left that threatens to cause serious difficulty; the wisdom of applying to it some such pleasing blanket term as "expressivism" remains to be demonstrated, especially since it is doubtful whether, in the last analysis, one can reduce the remaining forces to a single denominator. One nucleus that cannot by any stretch of the imagination be subsumed under either economy or clarity contains those formations associated with special moods—playful, tender, or festive. In contemporary English the colloquially flavored compositional types, such as *hush-hush*, *ping-pong*, *riffraff*, *wishy-washy*, *pribbles* and *prabbles*, *topsy-turvy*, *mumbo jumbo*—sometimes originating in the nursery and displaying a strong admixture of onomatopoeia—admirably fit this description. In Slavic and Romance languages, formations involving strings of hypocoristic suffixes would qualify as a counterpart. The

Hebrew spoken in modern Israel, the twentieth century's linguistic melting pot par excellence, allows speakers the jocose lapse into the Ashkenazic rather than the officially favored Sephardic pronunciation for proper names affectionately uttered, thus proliferating doublets. On the other hand, one runs across a phenomenon such as hypercharacterization (i.e., the sharper, more explicit, even uneconomically generous marking of a major grammatical category—say, gender, number, or person). For instance, the Latin *socrus* ("mother-in-law"), hampered by its conspicuously uncharacteristic *-us*, is more neatly profiled with regard to gender (and sex) at the Romance stage through a new and far more appropriate ending (Italian, *suocera*; Spanish, *suegra*, etc.); cf. also the change of Latin *puppis* ("poop," "stern"), marred by an ending indeterminate as to gender, into the clear-cut Spanish *pop-a*. In such instances, the change is, of course, analogical, but the driving force behind it seems less easy to identify. It certainly can be neither economy nor any overflow of emotion, and one is hesitant, to say the least, to press into service a quest for heightened clarity. The propelling force, one suspects, is the speaker's endeavor to redesign selected portions of the language, to make the medium of transmission more pointed or so silhouetted as to be aesthetically more satisfying. Sapir's reference to the "cut" of a language comes to mind here—a fait accompli or a goal toward which speakers may strive.

The most familiar external forces whose impact will produce the various types of linguistic change are those resulting from contact between languages (occasionally one living and the other dead, but preserved in ritual or intensely studied) or regional and social dialects. Typically, a protracted transitional period of thoroughgoing bilingualism or plurilingualism is needed before the contact produces sizable results. In gauging any such impact on a specific language, the historian tries first to determine the principal layer of that language by inspecting the core structure of its grammar and those ingredients of its lexicon best known for their resistance, if not total immunity, to infiltration. Numerals, kinship terms, names of parts of the body, and grammatically functional words are typical examples of such elements. Once this frame of reference has been established, it becomes clear which layers, in the course of further study, will be labeled substrata and which superstrata—eloquent metaphors borrowed from geology and permitting a graphic projection of anteriority. Thus, vis-à-vis Great Russian, the numerous Finno-Ugric languages, now extinct or pushed back to the periphery of eastern Europe, constituted substrata; so

did Coptic and, farther down the Nile valley in Egypt, the Greek *koinē* vis-à-vis Arabic, Frisian vis-à-vis Dutch in Holland, and French plus Canary Island Spanish vis-à-vis English in Louisiana. In the absence of any genuine symbiosis, it is doubtful whether American Indian languages may rank as substrata in relation to English in North America, as they indisputably do in relation to Spanish and Portuguese throughout Latin America. In the twilight hour between late Antiquity and the Middle Ages, Arabic in southern Spain and Frankish in northern Gaul represented superstrata in relation to divergent varieties of provincial Latin. To the extent that the Greeks tended to form independent cultural nuclei under the aegis of the expanding Roman Republic and later Roman Empire, their settlements qualify as examples of linguistic adstrata vis-à-vis Latin as well as the circum-Mediterranean indigenous languages.

Aside from such "vertical" relations, linguistic pressures operate "horizontally" across political borders and even at long distances through cultural diffusion. Thus, heavy clusters of Gallicisms are found not only in Spanish, Catalan, Italian, German, and Dutch, to say nothing of English, but also in languages occupying nonadjacent areas, such as Rumanian, Polish, Russian, and Swedish. Words are more easily borrowed than sounds, and affixes travel more rapidly than inflectional endings. A classic example of superimposed syntactic, semantic, and (probably) intonational patterns is provided by the multifarious Germanisms observable in eastern Switzerland's Romansh, a language descended from Raetian Latin.

Against the fairly trivial instances of direct, positive influence one may place the sorely neglected range of indirect or catalytic interferences. Thus, two early medieval Germanic kingdoms carved out of the ruins of the crumbling Roman Empire—that of the Suebi in Galician-Portuguese territory and that of the Burgundians in the Lyon-Geneva area—molded local Latin speech sparingly through loan words but exerted a powerful restraining influence by politically and culturally isolating their territories, at crucial junctures, from such centers of ceaseless linguistic innovation as Toledo and Paris.

An independent kind of external force comprises all sorts of nonlinguistic events potentially rich in linguistic reverberations. The invention of novel tools and machines may breathe new life into a moribund suffix serving to denote instruments. The emancipation of women the world over may develop dormant schemata (affixal, compositional, or otherwise derivational) for the designation of female agentials. A global vogue of formality or

familiarity (in clothing, dwellings, human relations, etc.) could hardly fail to revolutionize the system of forms of address and to affect even personal pronouns and possessive adjectives. The sections of the linguistic edifice most vulnerable to these influences are, then, the vocabulary, the derivational machinery (at the midway point between lexicon and grammar), plus a few pieces from the morphosyntactic tool kit.

Far beyond this boundary, the "idealistic" school of thought, entrenched in Italy and Germany only a generation ago (Vossler 1925), tended to assess very liberally the impact of changing modes of thinking on linguistic forms, extending that impact to the foundations of sentence structure. While the consensus of most generations of scholars has ascribed the disappearance of case endings to attrition, recognizing the rise of prepositional phrases as a relatively smooth replacement, the "idealists" preferred to view as prime mover the emergence of a new way of thinking (such as analytic rather than synthetic), crediting it with the manufacture of appropriate substitutes which eventually eroded the older grammatical framework. The advent of Christianity figured in these interpretations (especially in H. F. Muller's) as another favorite determinant of linguistic evolution. The idealistic position is thus diametrically opposed to that of Whorf, who, following Sapir (1921), mused that patterns of thinking may, in the first place, be molded by pre-existent grammatical structures.

The complex interaction of all these isolable forces can be illustrated with the differing, if reconcilable, answers to the classic question: What dooms a word to extinction? Plausible explanations offered either separately or in any number of free combinations include an excess of paradigmatic intricacy or phonological oddity in the fated word; the peril besetting the weaker of two conflicting homonyms; an intolerable dosage of polysemy; a sudden general demand at all levels of the given society for lexical rejuvenation or large-scale overhaul; the obsolescence of a specific cultural element (say, some container or garment) heretofore designated by the word at issue; the ineluctable effect of some socially controlled restriction (taboo, etc.); acceptance, through borrowing from the local prestige language, of a more attractive equivalent, as when the imported *Cousine* dislodged the native *Base* in eighteenth-century German.

Theories of linguistic change

For the projection of major phases of linguistic growth, and especially for signaling the relationship between cognate languages, experts in recon-

struction have resorted either to the somewhat older "family-tree theory" (*Stammbaumtheorie*) or to the wave hypothesis. The former is associated with the name of Schleicher, that contemporary and counterpart of the evolutionist Darwin who actually refined rather than launched the "family-tree" concept (1861). It operates with a filiation chart reminiscent of those long favored in the life sciences. The filiation chart, germane in its verbalization and, even more, in its graphic suggestion to the physicists' and chemists' views of radiation, cannot be traced to any advocate earlier than Schuchardt (1866) and, in particular, Schmidt (1871). The inherently rigid family-tree diagram presupposes uniform speech communities and their sudden and clear-cut bifurcation. The more elastic wave diagram tends to dissolve any system (or, less orderly, any arsenal) of communication tools into its constituents, granting to each change, whether phonetic, morphosyntactic, or lexical, its own scope and history. Neither the lapse of time it demands nor the area it covers need be exactly identical with those involved in any comparable change. The latest thinking sees in these divergent hypotheses two complementary projections, neither satisfactory if applied in isolation. Regrettably, no theory apt to reconcile them and no technique capable of smoothly integrating their separate findings have so far been devised.

The wave theory has intrinsically tended to give unusual prominence to the territorial expansion of linguistic features, providing the logical justification for linguistic (or dialect) geography. The interest in dialect geography is now past its crest; for many decades it fed on its sentimental motivation, local patriotism, and its partisans' delight in open-air field work. Practitioners of this approach developed special methods for interviews, oral or written questionnaires, and the cartographic recording of field notes (linguistic atlases). Dialect geographers endowed with historical flair then proceeded to transform the geographic patterns laboriously established into bolder chronological sequences, calling themselves the geologists, paleontologists, or stratigraphers of human speech.

One extreme formulation of these assumptions, tastes, and techniques (the "age-area hypothesis") relies chiefly or even exclusively on territorial patterns in piecing together temporal successions. An attempt to schematize these procedures of "areal analysis" was undertaken by the small group of Italian "neolinguists," a school that produced a short flurry of activity from 1920 to 1950. A point that has hitherto not been satisfactorily investigated and yet clamors for imaginative inquiry is

the wisdom of positing, alongside that "outer radiation" dear to dialect geographers and to diffusionists like Boas, some kind of "inner radiation" that might account in undulatory projections for the continuous restructuring of systems.

III THE SPEECH COMMUNITY

Although not all communication is linguistic, language is by far the most powerful and versatile medium of communication; all known human groups possess language. Unlike other sign systems, the verbal system can, through the minute refinement of its grammatical and semantic structure, be made to refer to a wide variety of objects and concepts. At the same time, verbal interaction is a social process in which utterances are selected in accordance with socially recognized norms and expectations. It follows that linguistic phenomena are analyzable both within the context of language itself and within the broader context of social behavior. In the formal analysis of language the object of attention is a particular body of linguistic data abstracted from the settings in which it occurs and studied primarily from the point of view of its referential function. In analyzing linguistic phenomena within a socially defined universe, however, the study is of language usage as it reflects more general behavior norms. This universe is the speech community: any human aggregate characterized by regular and frequent interaction by means of a shared body of verbal signs and set off from similar aggregates by significant differences in language usage.

Most groups of any permanence, be they small bands bounded by face-to-face contact, modern nations divisible into smaller subregions, or even occupational associations or neighborhood gangs, may be treated as speech communities, provided they show linguistic peculiarities that warrant special study. The verbal behavior of such groups always constitutes a system. It must be based on finite sets of grammatical rules that underlie the production of well-formed sentences, or else messages will not be intelligible. The description of such rules is a precondition for the study of all types of linguistic phenomena. But it is only the starting point in the sociolinguistic analysis of language behavior.

Grammatical rules define the bounds of the linguistically acceptable. For example, they enable us to identify "How do you do?" "How are you?" and "Hi" as proper American English sentences and to reject others like "How do you?" and "How you are?" Yet speech is not constrained by grammatical rules alone. An individual's choice from among permissible alternates in a particular speech event may reveal his family background and his social intent, may identify him as a Southerner, a Northerner, an urbanite, a rustic, a member of

the educated or uneducated classes, and may even indicate whether he wishes to appear friendly or distant, familiar or deferential, superior or inferior.

Just as intelligibility presupposes underlying grammatical rules, the communication of social information presupposes the existence of regular relationships between language usage and social structure. Before we can judge a speaker's social intent, we must know something about the norms defining the appropriateness of linguistically acceptable alternates for particular types of speakers; these norms vary among subgroups and among social settings. Wherever the relationships between language choice and rules of social appropriateness can be formalized, they allow us to group relevant linguistic forms into distinct dialects, styles, and occupational or other special parlanges. The sociolinguistic study of speech communities deals with the linguistic similarities and differences among these speech varieties.

In linguistically homogeneous societies the verbal markers of social distinctions tend to be confined to structurally marginal features of phonology, syntax, and lexicon. Elsewhere they may include both standard literary languages, and grammatically divergent local dialects. In many multilingual societies the choice of one language over another has the same signification as the selection among lexical alternates in linguistically homogeneous societies. In such cases, two or more grammars may be required to cover the entire scope of linguistically acceptable expressions that serve to convey social meanings.

Regardless of the linguistic differences among them, the speech varieties employed within a speech community form a system because they are related to a shared set of social norms. Hence, they can be classified according to their usage, their origins, and the relationship between speech and social action that they reflect. They become indices of social patterns of interaction in the speech community.

Historical orientation in early studies

Systematic linguistic field work began in the middle of the nineteenth century. Prior to 1940 the best-known studies were concerned with dialects, special parlanges, national languages, and linguistic acculturation and diffusion.

Dialectology. Among the first students of speech communities were the dialectologists, who charted the distribution of colloquial speech forms in societies dominated by German, French, English, Polish, and other major standard literary tongues. Mapping relevant features of pronunciation, gram-

mar, and lexicon in the form of *isoglosses*, they traced in detail the range and spread of historically documented changes in language habits. Isoglosses were grouped into bundles of two or more and then mapped; from the geographical shape of such isogloss bundles, it was possible to distinguish the *focal areas*, centers from which innovations radiate into the surrounding regions; *relic zones*, districts where forms previously known only from old texts were still current; and *transition zones*, areas of internal diversity marked by the coexistence of linguistic forms identified with competing centers of innovation.

Analysis along these lines clearly established the importance of social factors in language change. The distribution of rural speech patterns was found to be directly related to such factors as political boundaries during the preceding centuries, traditional market networks, the spread of important religious movements, etc. In this fashion dialectology became an important source of evidence for social history.

Special parlanges, classical languages. Other scholars dealt with the languages of occupationally specialized minority groups, craft jargons, secret argots, and the like. In some cases, such as the Romany of the gypsies and the Yiddish of Jews, these parlanges derive from foreign importations which survive as linguistic islands surrounded by other tongues. Their speakers tend to be bilinguals, using their own idiom for in-group communication and the majority language for interaction with outsiders.

Linguistic distinctness may also result from seemingly intentional processes of distortion. One very common form of secret language, found in a variety of tribal and complex societies, achieves unintelligibility by a process of verbal play with majority speech, in which phonetic or grammatical elements are systematically reordered. The pig Latin of English-speaking schoolchildren, in which initial consonants are transferred to the end of the word and followed by "-ay," is a relatively simple example of this process. Thieves' argots, the slang of youth gangs, and the jargon of traveling performers and other occupational groups obtain similar results by assigning special meanings to common nouns, verbs, and adjectives.

Despite their similarities, the classical administrative and liturgical languages—such as the Latin of medieval Europe, the Sanskrit of south Asia, and the Arabic of the Near East—are not ordinarily grouped with special parlanges because of the prestige of the cultural traditions associated with them.

They are quite distinct from and often unrelated to popular speech, and the elaborate ritual and etiquette that surround their use can be learned only through many years of special training. Instruction is available only through private tutors and is limited to a privileged few who command the necessary social status or financial resources. As a result, knowledge of these languages in the traditional societies where they are used is limited to relatively small elites, who tend to maintain control of their linguistic skills in somewhat the same way that craft guilds strive for exclusive control of their craft skills.

The standard literary languages of modern nation-states, on the other hand, tend to be representative of majority speech. As a rule they originated in rising urban centers, as a result of the free interaction of speakers of a variety of local dialects, became identified with new urban elites, and in time replaced older administrative languages. Codification of spelling and grammar by means of dictionaries and dissemination of this information through public school systems are characteristic of standard-language societies. Use of mass media and the prestige of their speakers tend to carry idioms far from their sources; such idioms eventually replace many pre-existing local dialects and special parlanges.

Linguistic acculturation, language shift. Whenever two or more speech communities maintain prolonged contact within a broad field of communication, there are crosscurrents of diffusion. The result is the formation of a *Sprachbund*, comprising a group of varieties which coexist in social space as dialects, distinct neighboring languages, or special parlanges. Persistent borrowing over long periods creates within such groups similarities in linguistic structure, which tend to obscure pre-existing genetic distinctions; a commonly cited example is the south Asian subcontinent, where speakers of Indo-Aryan, Dravidian, and Munda languages all show significant overlap in their linguistic habits.

It appears that single nouns, verbs, and adjectives are most readily diffused, often in response to a variety of technological innovations and cultural or religious trends. Pronunciation and word order are also frequently affected. The level of phonological and grammatical pattern (i.e., the structural core of a language), however, is more resistant to change, and loanwords tend to be adapted to the patterns of the recipient language. But linguistic barriers to diffusion are never absolute, and in situations of extensive bilingualism—

two or more languages being regularly used in the course of the daily routine—even the grammatical cores may be affected.

Cross-cultural influence reaches a maximum in the cases of pidgins and creoles, idioms combining elements of several distinct languages. These hybrids typically arise in colonial societies or in large trading centers where laborers torn out of their native language environments are forced to work in close cooperation with speakers of different tongues. Cross-cultural influence may also give rise to language shift, the abandonment of one native tongue in favor of another. This phenomenon most frequently occurs when two groups merge, as in tribal absorption, or when minority groups take on the culture of the surrounding majority.

Although the bulk of the research on speech communities that was conducted prior to 1940 is historically oriented, students of speech communities differ markedly from their colleagues who concentrate upon textual analysis. The latter tend to treat languages as independent wholes that branch off from uniform protolanguages in accordance with regular sound laws. The former, on the other hand, regard themselves primarily as students of behavior, interested in linguistic phenomena for their broader sociohistorical significance. By relating dialect boundaries to settlement history, to political and administrative boundaries, and to culture areas and by charting the itineraries of loanwords in relation to technical innovations or cultural movements, they established the primacy of social factors in language change, disproving earlier theories of environmental or biological determinism.

The study of language usage in social communities, furthermore, revealed little of the uniformity ordinarily ascribed to protolanguages and their descendants; many exceptions to the regularity of sound laws were found wherever speakers of genetically related languages were in regular contact. This led students of speech communities to challenge the "family-tree theory," associated with the neogrammarians of nineteenth-century Europe, who were concerned primarily with the genetic reconstruction of language history. Instead, they favored a theory of diffusion which postulates the spread of linguistic change in intersecting "waves" that emanate from different centers of innovation with an intensity proportionate to the prestige of their human carriers.

Thus, while geneticists regarded modern language distribution as the result of the segmentation of older entities into newer and smaller

subgroups, diffusionists viewed the speech community as a dynamic field of action where phonetic change, borrowing, language mixture, and language shift all occur because of social forces, and where genetic origin is secondary to these forces. In recent years linguists have begun to see the two theories as complementary. The assumption of uniformity among protolanguages is regarded as an abstraction necessary to explain existing regularities of sound change and is considered extremely useful for the elucidation of long-term prehistoric relationships, especially since conflicting short-term diffusion currents tend to cancel each other. Speech-community studies, on the other hand, appear better adapted to the explanation of relatively recent changes.

Language behavior and social communication

The shift of emphasis from historical to synchronic problems during the last three decades has brought about some fundamental changes in our theories of language, resulting in the creation of a body of entirely new analytical techniques. Viewed in the light of these fresh insights, the earlier speech-community studies are subject to serious criticism on grounds of both linguistic and sociological methodology. For some time, therefore, linguists oriented toward formal analysis showed very little interest. More recent structural studies, however, show that this criticism does not affect the basic concept of the speech community as a field of action where the distribution of linguistic variants is a reflection of social facts. The relationship between such variants when they are classified in terms of usage rather than of their purely linguistic characteristics can be examined along two dimensions: the *dialectal* and the *superposed*.

Dialectal relationships are those in which differences set off the vernaculars of local groups (for example, the language of home and family) from those of other groups within the same, broader culture. Since this classification refers to usage rather than to inherent linguistic traits, relationships between minority languages and majority speech (e.g., between Welsh and English in Britain or French and English in Canada) and between distinct languages found in zones of intensive intertribal contact (e.g., in modern Africa) can also be considered dialectal, because they show characteristics similar to the relationship existing between dialects of the same language.

Whereas dialect variation relates to distinctions in geographical origin and social background, superposed variation refers to distinctions between

different types of activities carried on within the same group. The special parlances described above form a linguistic extreme, but similar distinctions in usage are found in all speech communities. The language of formal speechmaking, religious ritual, or technical discussion, for example, is never the same as that employed in informal talk among friends, because each is a style fulfilling particular communicative needs. To some extent the linguistic markers of such activities are directly related to their different technical requirements. Scientific discussion, for instance, requires precisely defined terms and strict limitation on their usage. But in other cases, as in greetings, forms of address, or choosing between "isn't" and "ain't," the primary determinant is the social relationship between speakers rather than communicative necessity. Language choice in these cases is limited by social barriers; the existence of such barriers lends significance to the sociolinguistic study of superposed variation.

This distinction between dialectal and superposed varieties obviates the usual linguistic distinction between geographically and socially distributed varieties, since the evidence indicates that actual residence patterns are less important as determinants of distribution than social interaction patterns and usage. Thus, there seems to be little need to draw conceptual distinctions upon this basis.

Descriptions of dialectal and superposed variation relate primarily to social groups. Not all individuals within a speech community have equal control of the entire set of superposed variants current there. Control of communicative resources varies sharply with the individual's position within the social system. The more narrowly confined his sphere of activities, the more homogeneous the social environment within which he interacts, and the less his need for verbal facility. Thus, housewives, farmers, and laborers, who rarely meet outsiders, often make do with only a narrow range of speech styles, while actors, public speakers, and businessmen command the greatest range of styles. The fact that such individual distinctions are found in multilingual as well as in linguistically homogeneous societies suggests that the common assertion which identifies bilingualism with poor scores in intelligence testing is in urgent need of re-examination, based, as it is, primarily on work with underprivileged groups. Recent work, in fact, indicates that the failure of some self-contained groups to inculcate facility in verbal manipulation is a major factor in failures in their children's performances in public school systems.

Attitudes to language choice. Social norms of language choice vary from situation to situation and from community to community. Regularities in attitudes to particular speech varieties, however, recur in a number of societies and deserve special comment here. Thieves' argots, gang jargons, and the like serve typically as group boundary maintaining mechanisms, whose linguistic characteristics are the result of informal group consensus and are subject to continual change in response to changing attitudes. Individuals are accepted as members of the group to the extent that their usage conforms to the practices of the day. Similar attitudes of exclusiveness prevail in the case of many tribal languages spoken in areas of culture contact where other superposed idioms serve as media of public communication. The tribal language here is somewhat akin to a secret ritual, in that it is private knowledge to be kept from outsiders, an attitude which often makes it difficult for casual investigators to collect reliable information about language distribution in such areas.

Because of the elaborate linguistic etiquette and stylistic conventions that surround them, classical, liturgical, and administrative languages function somewhat like secret languages. Mastery of the conventions may be more important in gaining social success than substantive knowledge of the information dispensed through these languages. But unlike the varieties mentioned above, norms of appropriateness are explicit in classical languages; this permits them to remain unchanged over many generations.

In contrast, the attitude to pidgins, trade languages, and similar intergroup media of communication tends to be one of toleration. Here little attention is paid to linguistic markers of social appropriateness. It is the function of such languages to facilitate contact between groups without constituting their respective social cohesiveness; and, as a result, communication in these languages tends to be severely restricted to specific topics or types of interaction. They do not, as a rule, serve as vehicles for personal friendships.

We speak of *language loyalty* when a literary variety acquires prestige as a symbol of a particular nationality group or social movement. Language loyalty tends to unite diverse local groups and social classes, whose members may continue to speak their own vernaculars within the family circle. The literary idiom serves for reading and for public interaction and embodies the cultural tradition of a nation or a sector thereof. Individuals choose to employ it as a symbol

of their allegiance to a broader set of political ideals than that embodied in the family or kin group.

Language loyalty may become a political issue in a modernizing society when hitherto socially isolated minority groups become mobilized. Their demands for closer participation in political affairs are often accompanied by demands for language reform or for the rewriting of the older, official code in their own literary idiom. Such demands often represent political and socioeconomic threats to the established elite, which may control the distribution of administrative positions through examination systems based upon the official code. The replacement of an older official code by another literary idiom in modernizing societies may thus represent the displacement of an established elite by a rising group.

The situation becomes still more complex when socioeconomic competition between several minority groups gives rise to several competing new literary standards, as in many parts of Asia and Africa, where language conflicts have led to civil disturbances and political instability. Although demands for language reform are usually verbalized in terms of communicative needs, it is interesting to observe that such demands do not necessarily reflect important linguistic differences between the idioms in question. Hindi and Urdu, the competing literary standards of north India, or Serbian and Croatian, in Yugoslavia, are grammatically almost identical. They differ in their writing systems, in their lexicons, and in minor aspects of syntax. Nevertheless, their proponents treat them as separate languages. The conflict in language loyalty may even affect mutual intelligibility, as when speakers' claims that they do not understand each other reflect primarily social attitudes rather than linguistic fact. In other cases serious linguistic differences may be disregarded when minority speakers pay language loyalty to a standard markedly different from their own vernacular. In many parts of Alsace-Lorraine, for example, speakers of German dialects seem to disregard linguistic fact and pay language loyalty to French rather than to German.

Varietal distribution. Superposed and dialectal varieties rarely coincide in their geographical extent. We find the greatest amount of linguistic diversity at the level of local, tribal, peasant, or lower-class urban populations. Tribal areas typically constitute a patchwork of distinct languages, while local speech distribution in many modern nations takes the form of a dialect chain in which the speech of each locality is similar to that of

adjoining settlements and in which speech differences increase in proportion to geographical distance. Variety at the local level is bridged by the considerably broader spread of superposed varieties, serving as media of supralocal communication. The Latin of medieval Europe and the Arabic of the Near East form extreme examples of supralocal spread. Uniformity at the superposed level in their case, however, is achieved at the expense of large gaps in internal communication channels. Standard languages tend to be somewhat more restricted in geographical spread than classical languages, because of their relationship to local dialects. In contrast to a society in which classical languages are used as superposed varieties, however, a standard-language society possesses better developed channels of internal communication, partly because of its greater linguistic homogeneity and partly because of the internal language loyalty that it evokes.

In fact, wherever standard languages are well-established they act as the ultimate referent that determines the association of a given local dialect with one language or another. This may result in the anomalous situation in which two linguistically similar dialects spoken on different sides of a political boundary are regarded as belonging to different languages, not because of any inherent linguistic differences but because their speakers pay language loyalty to different standards. Language boundaries in such cases are defined partly by social and partly by linguistic criteria.
